The aim of this project is to provide a platform for testing **DRAM vulnerability to rowhammer attacks**.

1.1 Architecture

The setup consists of FPGA gateware and application side software. The following diagram illustrates the general system architecture.

The DRAM is connected to **LiteDRAM**, which provides swappable PHYs and a DRAM controller implementation.

In the default bulk transfer mode the LiteDRAM controller is connected to PHY and ensures correct DRAM traffic. Bulk transfers can be controlled using dedicated Control & Status Registers (CSRs) and use LiteDRAM DMA to ensure fast operation.

The Payload Executor allows executing a user-provided sequence of commands. It temporarily disconnects the DRAM controller from PHY, executes the instructions stored in the SRAM memory, translating them into DFI commands and finally reconnects the DRAM controller.

The application side consists of a set of Python scripts communicating with the FPGA using the LiteX EtherBone bridge.

1.2 Installing dependencies

Make sure you have Python 3 installed with the venv module, and the dependencies required to build [verilator](#), [openFPGALoader](#) and [OpenOCD](#). To install the dependencies on Ubuntu 18.04 LTS, run:

```
apt install git build-essential autoconf cmake flex bison libftdi-dev libjson-c-  
↳dev libevent-dev libtinfo-dev uclibc-headers python3 python3-venv python3-wheel_  
↳protobuf-compiler libcairo2 libftdi1-2 libftdi1-dev libhidapi-hidraw0 libhidapi-  
↳dev libudev-dev pkg-config tree zlib1g-dev zip unzip help2man curl ethtool
```

Note: On some Debian-based systems there's a problem with a broken dependency:

```
libc6-dev : Breaks: libgcc-9-dev (< 9.3.0-5~) but 9.2.1-19 is to be installed
```

gcc-9-base package installation solves the problem.

On Ubuntu 22.04 LTS the following dependencies may also be required:

```
apt install libtool libusb-1.0-0-dev pkg-config
```

1.2.1 Rowhammer tester

Now clone the rowhammer-tester repository and install the rest of the required dependencies:

```
git clone --recursive https://github.com/antmicro/rowhammer-tester.git  
cd rowhammer-tester  
make deps
```

The last command will download and build all the dependencies (including a RISC-V GCC toolchain) and will set up a **Python virtual environment** under the `./venv` directory with all the required packages installed.

The virtual environment allows you to use Python without installing the packages system-wide. To enter the environment, you have to run `source venv/bin/activate` in each new shell. You can also use the provided `make env` target, which will start a new Bash shell with the virtualenv already sourced. You can install packages inside the virtual environment by entering the environment and then using `pip`.

To build the bitstream you will also need to have Vivado (version 2020.2 or newer) installed and the `vivado` command available in your `PATH`. To configure Vivado in the current shell, you need to source `/PATH/TO/Vivado/VERSION/settings64.sh`. This can be put in your `.bashrc` or other shell init script.

To make the process automatic without hard-coding these things in shell init script, tools like `direnv` can be used. A sample `.envrc` file would then look like this:

```
source venv/bin/activate  
source /PATH/TO/Vivado/VERSION/settings64.sh
```

All other commands assume that you run Python from the virtual environment with vivado in your PATH.

1.3 Packaging the bitstream

If you want to save the bitstream and use it later or share it with someone, there is an utility target `make pack`. It packs files necessary to load the bitstream and run rowhammer scripts on it. Those files are:

- `build/$TARGET/gateway/$TOP.bit`
- `build/$TARGET/csr.csv`
- `build/$TARGET/defs.csv`
- `build/$TARGET/sdram_init.py`
- `build/$TARGET/litedram_settings.json`

After running `make pack`, you should have a zip file named like `$TARGET-$BRANCH-$COMMIT.zip`.

Next time you want to use a bitstream packaged in such way, all you need to do is to run `unzip your-bitstream-file.zip` and you are all set.

1.4 Local documentation build

The gateway part of the documentation is auto-generated from source files. Other files are static and are located in the `doc/` directory. To build the documentation, enter:

```
source venv/bin/activate
pip install -r requirements.txt
python -m sphinx -b html doc build/documentation/html
```

The documentation will be located in `build/documentation/index.html`.

Note: For easier development one can use `sphinx-autobuild` using command `sphinx-autobuild -b html doc build/documentation/html --re-ignore 'doc/build/*'`. The documentation can be then viewed in a browser at `http://127.0.0.1:8000`.

1.5 Tests

To run project tests use:

```
make test
```

This tool can be run on real hardware (FPGAs) or in a simulation mode. As the rowhammer attack exploits physical properties of cells in DRAM (draining charges), no bit flips can be observed in simulation mode. However, the simulation mode is useful to test command sequences during the development.

The Makefile can be configured using environmental variables to modify the network configuration used and to select the target. Currently, 4 boards are supported, each targeting different memory type:

Board	Memory type	TARGET
Arty A7	DDR3	arty
ZCU104	DDR4 (SO-DIMM)	zcu104
DDR Datacenter DRAM Tester	DDR4 (RDIMM)	ddr4_datacenter_test_board
LPDDR4 Test Board	LPDDR4 (SO-DIMM)	lpddr4_test_board
DDR5 Tester	DDR5 (RDIMM)	ddr5_tester
DDR5 Test Board	DDR5 (SO-DIMM)	ddr5_test_board

Note: Although you choose a target board for the simulation, it doesn't require having a physical board. Simulation is done entirely on your computer.

For board-specific instructions refer to *Arty A7*, *ZCU104*, *DDR4 Datacenter DRAM Tester*, *LPDDR4 Test Board*, *DDR5 Tester* and *DDR5 Test Board* chapters. The rest of this chapter describes operations that are common for all supported boards.

2.1 Network USB adapter setup

In order to control the Rowhammer platform an Ethernet connection is necessary. In case you want to use an USB Ethernet adapter for this purpose read the instructions below.

1. Make sure you use a 1GbE USB network adapter
2. Figure out the MAC address for the USB network adapter:
 - Run `sudo lshw -class network -short` to get the list of all network interfaces
 - Check which of the devices uses the r8152 driver by running `sudo ethtool -i <device>`

- Display the link information for the device running `sudo ip link show <device>` and look for the mac address next to the link/ether field
3. Configure the USB network adapter to appear as network device `fpga0` using `systemd`
 - Create `/etc/systemd/network/10-fpga0.link` with the following contents:

```
[Match]
# Set this to the MAC address of the USB network adapter
MACAddress=XX:XX:XX:XX:XX

[Link]
Name=fpga0
```

4. Configure the `fpga0` network device with a static IP address, always up (even when disconnected) and ignored by the network manager.

- Run the following command, assuming your system uses NetworkManager

```
nmcli con add type ethernet con-name 'Rowhammer Tester' ifname fpga0_
↳ ipv4.method manual ipv4.addresses 192.168.100.100/24
```

- Alternatively, if your system supports legacy interfaces configuration file:

1. Make sure your `/etc/network/interfaces` file has the following line:

```
source /etc/network/interfaces.d/*
```

2. Create `/etc/network/interfaces.d/fpga0` with the following contents:

```
auto fpga0
allow-hotplug fpga0
iface fpga0 inet static
    address 192.168.100.100/24
```

3. Check that `nmcli` device says the state is connected (externally) otherwise run `sudo systemctl restart NetworkManager`

- Run `ifup fpga0`

5. Run `sudo udevadm control --reload` and then unplug the USB ethernet device and plug it back in
6. Check you have an `fpga0` interface and it has the correct IP address by running `networkctl status`

Note: In case you see `libusb_open()` failed with `LIBUSB_ERROR_ACCESS` when trying to use the rowhammer tester scripts with the USB ethernet adapter then it means that you have a permissions issue and need to allow access to the FTDI USB to serial port chip. Check the group listed for the tty's when running `ls -l /dev/ttyUSB*` and add the current user to this group by running `sudo adduser <username> <group>`.

2.2 Controlling the board

Board control is the same for both simulation and hardware runs. In order to communicate with the board via EtherBone, the `litex_server` needs to be started with the following command:

```
export IP_ADDRESS=192.168.100.50 # optional, should match the one used during_
↳build
make srv
```

Warning: If you want to run the simulation and the rowhammer scripts on a physical board at the same time, you have to change the `IP_ADDRESS` variable, otherwise the simulation can conflict with the communication with your board.

The build files (CSRs address list) must be up to date. It can be re-generated with `make` without arguments.

Then, in another terminal, you can use the Python scripts provided. *Remember to enter the Python virtual environment before running the scripts!* Also, the `TARGET` variable should be set to load configuration for the given target. For example, to use the `leds.py` script, run the following:

```
source ./venv/bin/activate
export TARGET=arty # (or zcu104) required to load target configuration
cd rowhammer_tester/scripts/
python leds.py # stop with Ctrl-C
```

2.3 Hammering

Rowhammer attacks can be run against a DRAM module. It can be then used for measuring cell retention. For the complete list of scripts' modifiers, see `--help`.

There are two versions of a rowhammer script:

- `rowhammer.py` - this one uses regular memory access via EtherBone to fill/check the memory (slower)
- `hw_rowhammer.py` - BIST blocks will be used to fill/check the memory (much faster, but with some limitations regarding fill pattern)

BIST blocks are faster and are the intended way of running Rowhammer tester.

Hammering of a row is done by reading it. There are two ways to specify a number of reads:

- `--read_count N` - one pass of N reads
- `--read_count_range K M N` - multiple passes of reads, as generated by `range(K, M, N)`

Regardless of which one is used, the number of reads in one pass is divided equally between hammered rows. If a user specifies `--read_count 1000`, then each row will be hammered 500 times.

Normally hammering is being performed via DMA, but there is also an alternative way with `--payload-executor`. It bypasses the DMA and directly talks with the PHY. That allows the user to issue specific activation, refresh and precharge commands.

2.3.1 Attack modes

Different attack and row selection modes can be used, but only one of them can be specified at the same time.

- `--hammer-only`

Only hammers rows, without doing any error checks or reports. When run with `rowhammer.py` the attack is limited to one row pair. `hw_rowhammer.py` can attack up to 32 rows. With `--payload-executor` enabled the row limit is dictated by the payload memory size.

For example following command will hammer rows 4 and 6 1000 times total (so 500 times each):

```
(venv) $ python hw_rowhammer.py --hammer-only 4 6 --read_count 1000
```

- `--all-rows`

Row pairs generated from `range(start-row, nrows - row-pair-distance, row-jump)` expression will be hammered.

Generated pairs are of form `(i, i + row-pair-distance)`. Default values for used arguments are:

argument	default
<code>--start-row</code>	0
<code>--row-jump</code>	1
<code>--row-pair-distance</code>	2

So you can run following command to hammer rows `(0, 2)`, `(1, 3)`, `(2, 4)`:

```
(venv) $ python hw_rowhammer.py --all-rows --nrows 5
```

And in case of:

```
(venv) $ python hw_rowhammer.py --all-rows --start-row 10 --nrows 16 --row-  
↪jump 2 --row-distance 3
```

hammered pairs would be: `(10, 13)`, `(12, 15)`.

In a special case, where `--row-pair-distance` is 0, you can check how hammering a single row affects other rows. Normally activations and deactivations are achieved with row reads using the DMA, but in this case it is not possible. Because the same row is being read all the time, no deactivation command would be sent by the DMA. In this case, `--payload-executor` is required as it bypasses the DMA and sends deactivation commands on its own.

```
(venv) $ python hw_rowhammer.py --all-rows --nrows 5 --row-pair-distance 0 --  
↳payload-executor
```

- `--row-pairs sequential`

Hammers pairs of (start-row, start-row + n), where n is from 0 to nrows.

```
(venv) $ python hw_rowhammer.py --row-pairs sequential --start-row 4 --nrows_  
↳10
```

Command above, would hammer following set of row pairs:

```
(4, 4 + 0)  
(4, 4 + 1)  
...  
(4, 4 + 9)  
(4, 4 + 10)
```

- `--row-pairs const`

Two rows specified with the `const-rows-pair` parameter will be hammered:

```
(venv) $ python hw_rowhammer.py --row-pairs const --const-rows-pair 4 6
```

- `--row-pairs random`

nrows pairs of random rows will be hammered. Row numbers will be between start-row and start-row + nrows.

```
(venv) $ python hw_rowhammer.py --row-pairs random --start-row 4 --nrows 10
```

- `--no-attack-time <time>`

Instead of performing a rowhammer attack, the script will load the RAM with selected pattern and sleep for time nanoseconds. After this time, it will check for any bitflips that could have happened. This option does not imply `--no-refresh`!

```
(venv) $ python hw_rowhammer.py --no-attack-time 100e9 --no-refresh
```

2.3.2 Patterns

User can choose a pattern that memory will be initially filled with:

- `all_0` - all bits set to 0
- `all_1` - all bits set to 1
- `01_in_row` - alternating 0's and 1's in a row (0xaaaaaaaa in hex)
- `01_per_row` - all 0's in odd-numbered rows, all 1's in even rows
- `rand_per_row` - random values for all rows

2.3.3 Example output

```
(venv) $ python hw_rowhammer.py --nrows 512 --read_count 10e6 --pattern 01_in_row_
↳--row-pairs const --const-rows-pair 54 133 --no-refresh

Bit-flips for row 132: 12
Bit-flips for row 134: 3
```

2.3.4 Row selection examples

Warning: Attacks are performed on a single bank. By default it is bank 0. To change the bank that is being attacked use the `--bank` flag.

- Select row pairs from row 3 (`--start-row`) to row 59 (`--nrows`) where the next pair is 5 rows away (`--row-jump`) from the previous one:

```
(venv) $ python hw_rowhammer.py --pattern 01_in_row --all-rows --start-row 3_
↳--nrows 60 --row-jump 5 --no-refresh --read_count 10e4
```

- Select row pairs from row 3 to row 59 without a distance between subsequent pairs (no `--row-jump`), which means that rows pairs are incremented by 1:

```
(venv) $ python hw_rowhammer.py --pattern 01_in_row --all-rows --start-row 3_
↳--nrows 60 --no-refresh --read_count 10e4
```

- Select all row pairs (from 0 to `nrows - 1`):

```
(venv) $ python hw_rowhammer.py --pattern 01_in_row --all-rows --nrows 512 --
↳no-refresh --read_count 10e4
```

- Select all row pairs (from 0 to `nrows - 1`) and save the error summary in JSON format to the test directory:

```
(venv) $ python hw_rowhammer.py --pattern 01_in_row --all-rows --nrows 512 --no-refresh --read_count 10e4 --log-dir ./test
```

- Select only one row (42 in this case) and save the error summary in JSON format to the test directory:

```
(venv) $ python hw_rowhammer.py --pattern all_1 --row-pairs const --const-rows-pair 42 42 --no-refresh --read_count 10e4 --log-dir ./test
```

- Select all rows (from 0 to nrows - 1) and hammer them one by one 1M times each.

```
(venv) $ python hw_rowhammer.py --all-rows --nrows 100 --row-pair-distance 0 --payload-executor --no-refresh --read_count 1e6
```

Note: Since for a single ended attack row activation needs to be triggered the `--payload-executor` switch is required. The size of the payload memory is set by default to 1024 bytes and can be changed using the `--payload-size` switch.

2.3.5 Cell retention measurement examples

- Select all row pairs (from 0 to nrows - 1) and perform a set of tests for different read count values, starting from 10e4 and ending at 10e5 with a step of 20e4 (`--read_count_range [start stop step]`):

```
(venv) $ python hw_rowhammer.py --pattern 01_in_row --all-rows --nrows 512 --no-refresh --read_count_range 10e4 10e5 20e4
```

- Perform set of tests for different read count values in a given range for one row pair (50, 100):

```
(venv) $ python hw_rowhammer.py --pattern 01_in_row --row-pairs const --const-rows-pair 50 100 --no-refresh --read_count_range 10e4 10e5 20e4
```

- Perform set of tests for different read count values in a given range for one row pair (50, 100) and stop the test execution as soon as a bitflip is found:

```
(venv) $ python hw_rowhammer.py --pattern 01_in_row --row-pairs const --const-rows-pair 50 100 --no-refresh --read_count_range 10e4 10e5 20e4 --exit-on-bit-flip
```

- Perform set of tests for different read count values in a given range for one row pair (50, 100) and save the error summary in JSON format to the test directory:

```
(venv) $ python hw_rowhammer.py --pattern 01_in_row --row-pairs const --const-rows-pair 50 100 --no-refresh --read_count_range 10e4 10e5 20e4 --log-dir ./test
```

- Perform set of tests for different read count values in a given range for a sequence of attacks for different pairs, where the first row of a pair is 40 and the second one is a row of a number from range (40, nrows - 1):

```
(venv) $ python hw_rowhammer.py --pattern 01_in_row --row-pairs sequential --  
↪start-row 40 --nrows 512 --no-refresh --read_count_range 10e4 10e5 20e4
```

2.4 Utilities

Some of the scripts are simple and do not take command line arguments, others will provide help via `<script_name>.py --help` or `<script_name>.py -h`.

Few of the scripts accept a `--srv` option. With this option enabled, a program will start it's own instance of `litex_server` (the user doesn't need to run `make srv` to *control the board*)

2.4.1 Run LEDs demo - `leds.py`

Displays a simple “bouncing” animation using the LEDs on Arty-A7 board, with the light moving from side to side.

`-t TIME_MS` or `--time-ms TIME_MS` option can be used to adjust LED switching interval.

2.4.2 Check version - `version.py`

Prints the data stored in the LiteX identification memory:

- hardware platform identifier
- source code git hash
- build date

Example output:

```
(venv) python version.py  
Rowhammer tester SoC on xc7k160tffg676-1, git:↪  
↪e7854fdd16d5f958e616bbb4976a97962ee9197d 2022-07-24 15:46:52
```

2.4.3 Check CSRs - `dump_regs.py`

Dumps values of all CSRs. Example output of `dump_regs.py`:

```
0x82000000: 0x00000000 ctrl_reset  
0x82000004: 0x12345678 ctrl_scratch  
0x82000008: 0x00000000 ctrl_bus_errors  
0x82002000: 0x00000000 uart_rxtx  
0x82002004: 0x00000001 uart_txfull  
0x82002008: 0x00000001 uart_rxempty  
0x8200200c: 0x00000003 uart_ev_status  
0x82002010: 0x00000000 uart_ev_pending  
...
```

Note: Note that `ctrl_scratch` value is `0x12345678`. This is the reset value of this register. If you are getting a different, this may indicate a problem.

2.4.4 Initialize memory - `mem.py`

Before the DRAM memory can be used, the initialization and leveling must be performed. The `mem.py` script serves this purpose.

Expected output:

```
(venv) $ python mem.py
(LiteX output)
----- Initialization -----
Initializing SDRAM @0x40000000...
Switching SDRAM to software control.
Read leveling:
  m0, b0: |11111111111100000000000000000000| delays: 06+-06
  m0, b1: |00000000000000111111111111111000| delays: 21+-08
  m0, b2: |00000000000000000000000000000001| delays: 31+-01

```

2.4.5 Enter BIOS - bios_console.py

Sometimes it may happen that memory initialization fails when running the `mem.py` script. This is most likely due to using boards that allow to swap memory modules, such as ZCU104.

Memory initialization procedure is performed by the CPU instantiated inside the FPGA fabric. The CPU runs the LiteX BIOS. In case of memory training failure it may be helpful to access the LiteX BIOS console.

If the script cannot find a serial terminal emulator program on the host system, it will fall back to `litex_term` which is shipped with LiteX. It is however advised to install `picocom/minicom` as `litex_term` has worse performance.

In the BIOS console use the `help` command to get information about other available commands. To re-run memory initialization and training type `reboot`.

Note: To close `picocom/minicom` enter CTRL+A+X key combination.

Example:

```
(venv) $ python bios_console.py
LiteX Crossover UART created: /dev/pts/4
Using serial backend: auto
picocom v3.1

Perform memory tests from the BIOS

After entering the BIOS, you may want to perform a memory test using utilities built into the BIOS itself. There are a couple ways to do such:

- `mem_test` - performs a series of writes and reads to check if values read back are the same as those previously written. It is limited by a 32-bit address bus, so only 4 GiB of address space can be tested. You can get origin of the RAM space using `mem_list` command.
- `sdram_test` - basically `mem_test`, but predefined for first 1/32 of defined RAM region size.
- `sdram_hw_test` - similar to `mem_test`, but accesses the SDRAM directly using DMAs, so it is not limited to 4 GiB. It requires passing 2 arguments (`origin` and `size`) with a 3rd optional argument being `burst_length`. When using `sdram_hw_test` you don't have to offset the origin like in the case of `mem_test`. `size` is a number of bytes to test and `burst_length` is a number of full transfer writes to the SDRAM, before reading and checking written content. The default value for `burst_length` is 1, which means that after every write, a check is performed. Generally, bigger `burst_length` means faster operation.

2.4.6 Test with BIST - `mem_bist.py`

A script written to test BIST block functionality. Two tests are available:

- `test-modules` - memory is initialized and then a series of errors is introduced (on purpose). Then BIST is used to check the content of the memory. If the number of errors detected is equal to the number of errors introduced, the test is passed.
- `test-memory` - simple test that writes a pattern in the memory, reads it, and checks if the content is correct. Both write and read operations are done via BIST.

2.4.7 Run benchmarks - benchmark.py

Benchmarks memory access performance. There are two subcommands available:

- etherbone - measure performance of the EtherBone bridge
- bist - measure performance of DMA DRAM access using the BIST modules

Example output:

```
(venv) $ python benchmark.py etherbone read 0x10000 --burst 255
Using generated target files in: build/lpddr4_test_board
Running measurement ...
Elapsed = 4.189 sec
Size = 256.000 KiB
Speed = 61.114 KiBps

(venv) $ python benchmark.py bist read
Using generated target files in: build/lpddr4_test_board
Filling memory before reading measurements ...
Progress: [=====] 16777216 / 16777216
Running measurement ...
Progress: [=====] 16777216 / 16777216 (Errors: 0)
Elapsed = 1.591 sec
Size = 512.000 MiB
Speed = 321.797 MiBps
```

2.4.8 Use logic analyzer - analyzer.py

This script utilizes the Litescope functionality to gather debug information about signals in the LiteX system. In-depth Litescope documentation [is here](#).

As you can see in Litescope documentation, Litescope analyzer needs to be instantiated in your design. Example design with analyzer added was provided as `arty_litescope` TARGET. As the name implies it can be run using Arty board. You can use `rowhammer_tester/targets/arty_litescope.py` as a reference for your own Litescope-enabled targets.

To build `arty_litescope` example and upload it to device, follow instructions below:

1. In root directory run:

```
export TARGET=arty_litescope
make build
make upload
```

`analyzer.csv` file will be created in the root directory.

2. We need to copy it to target's build dir before using `analyzer.py`.

```
cp analyzer.csv build/arty_litescope/
```

3. Then start `litex-server` with:

```
make srv
```

4. And execute analyzer script in a separate shell:

```
export TARGET=arty_litescope  
python rowhammer_tester/scripts/analyzer.py
```

Results will be stored in dump.vcd file and can be viewed with gtkwave:

```
gtkwave dump.vcd
```

2.5 Simulation

Select TARGET, generate intermediate files & run simulation:

```
export TARGET=arty # (or zcu104)  
make sim
```

This command will generate intermediate files & simulate them with Verilator. After simulation has finished, a signals dump can be investigated using [gtkwave](#):

```
gtkwave build/$TARGET/gateway/sim.fst
```

Warning: The repository contains a wrapper script around sudo which disallows LiteX to interfere with the host network configuration. This forces the user to manually configure a TUN interface for valid communication with the simulated device.

1. Create the TUN interface:

```
tunctl -u $USER -t litex-sim
```

2. Configure the IP address of the interface:

```
ifconfig litex-sim 192.168.100.1/24 up
```

3. Optionally allow network traffic on this interface:

```
iptables -A INPUT -i litex-sim -j ACCEPT  
iptables -A OUTPUT -o litex-sim -j ACCEPT
```

Note: Typing `make ARGS="--sim"` will cause LiteX to generate only intermediate files and stop right after that.

VISUALIZATION

If you have already executed some attacks on your board you can use the results to draw a plot or visualize it in the [F4PGA Database Visualizer](#).

3.1 Plot bitflips - logs2plot.py

This script can plot graphs out of generated logs. It can generate two different types of graphs:

1. Distribution of bitflips across rows and columns. For example, you can generate some graphs by calling:

```
(venv) $ python logs2plot.py your_error_summary.json
```

One graph will be generated for every attack. So if you attacked two row pairs (A, B), (C, D) with two different read counts each (X, Y), for a total of 4 attacks, you will get 4 plots:

- read count: X and pair: (A, B)
- read count: X and pair: (C, D)
- read count: Y and pair: (A, B)
- read count: Y and pair: (C, D)

You can control the number of displayed columns with `--plot-columns`. For example if your module has 1024 columns and you provide `--plot-columns 16`, then the DRAM columns will be displayed in groups of 64.

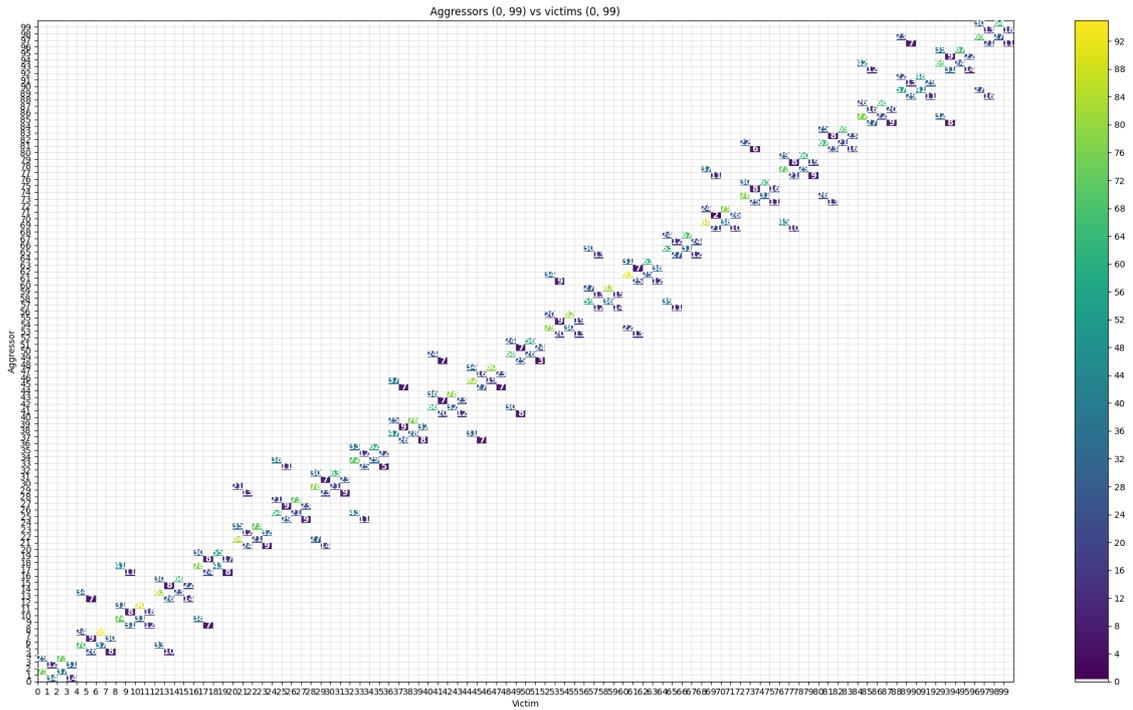

2. Distribution of rows affected by bitflips due to targeting single rows. For example one can generate a graph by calling:

```
(venv) $ python logs2plot.py --aggressors-vs-victims your_error_summary.  
↪.json
```

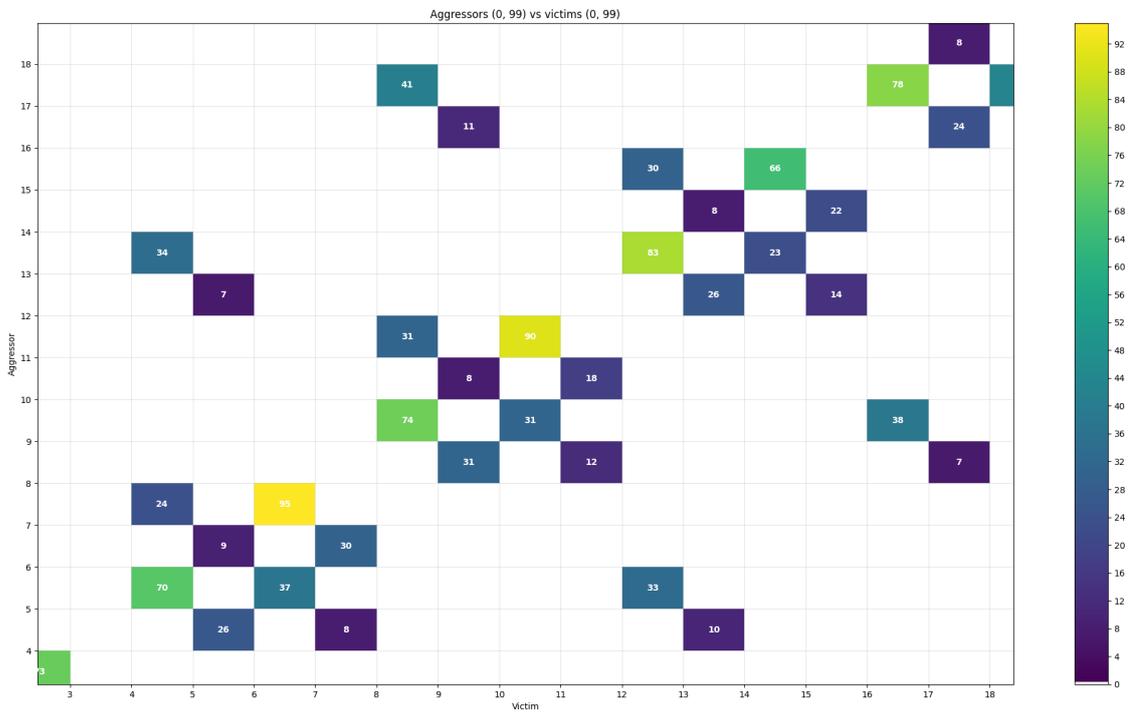

One graph will be generated with victims on the X axis and aggressors on the Y axis. The colors of the tiles indicate how many bitflips occurred on each victim.

You can enable additional annotation with `--annotate bitflips` so that the number of occurred bitflips will be explicitly labeled on top of each victim tile.

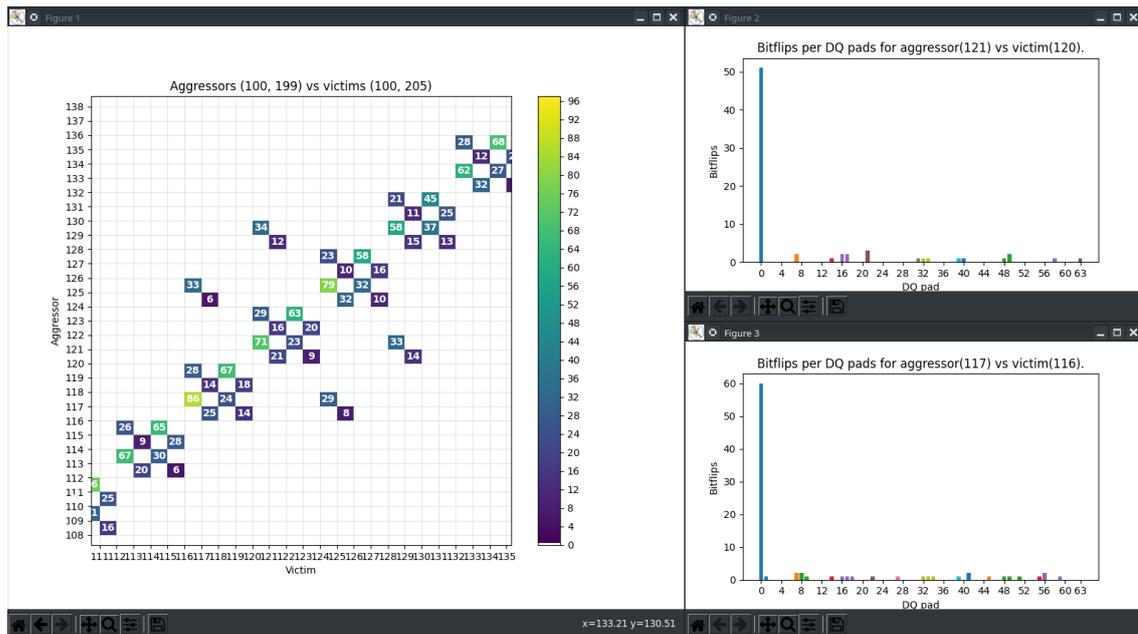

Example plot generated with annotation enabled:

You can zoom-in on interesting parts by using a matplotlib's zoom tool (in the bottom left corner):

This type of plot has built-in DQ per pad statistics for each attack. After clicking a specific tile you will see a new pop-up window with a plot:

3.2 Plot per DQ pad - logs2dq.py

This script allows you to visualize bitflips and group them per DQ pad. Pads themselves are grouped using colors to differentiate modules. Using this script you can visualize and check which module is failing the most.

By default it shows you mean bitflips across all attacks with standard deviation.

First run `rowhammer.py` or `hw_rowhammer.py` with the `--log-dir log_directory` flag.

Then run:

```
python3 logs2dq.py log_directory/your_error_summary.json
```

You can also pass optional arguments:

- `--dq DQ` - how many pads are connected to one module
- `--per-attack` - allows you to also view DQ groupings for each attacked pair of rows

3.3 Use F4PGA Visualizer - logs2vis.py

Similarly to `logs2plot.py`, you can generate visualizations using the [F4PGA Database Visualizer](#).

To view results using the visualizer you need to:

1. Clone and build the visualizer with:

```
git clone https://github.com/chipsalliance/f4pga-database-visualizer
cd f4pga-database-visualizer
npm run build
```

2. Run `rowhammer.py` or `hw_rowhammer.py` with `--log-dir log_directory`

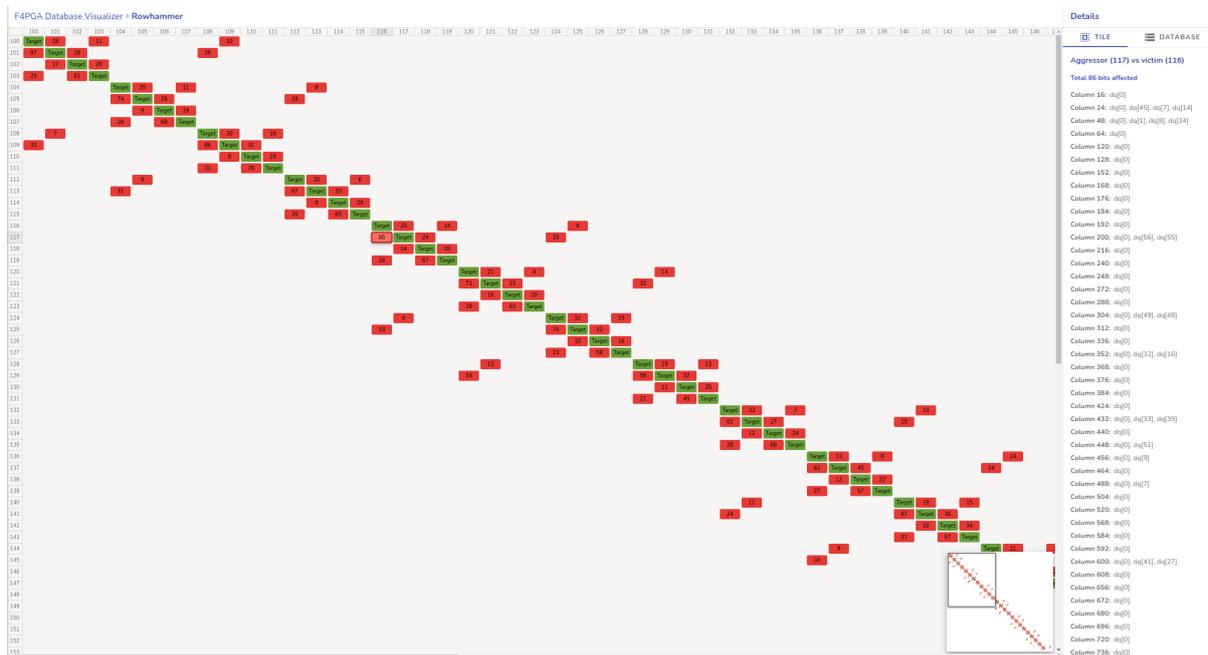

Generate JSON files for the visualizer:

```
python3 logs2vis.py log_directory/your_error_summary.json vis_directory
```

3. Copy generated JSON files from `vis_directory` to `/path/to/f4pga-database-visualizer/dist/production/`
4. Start a simple HTTP server inside the production directory:

```
python -m http.server 8080
```

An example output generated with the `--aggressors-vs-victims` flag looks like this:

The [Playbook directory](#) contains a group of Python classes and scripts designed to simplify the process of writing various rowhammer-related tests. These tests can be executed against a hardware platform.

4.1 Payload

Tests are generated as payload data. After generation, this data is transferred to a memory area in the device reserved for this purpose called payload memory. The payload contains an instruction list that can be interpreted by the payload executor module in hardware. The payload executor translates these instructions into DRAM commands. The payload executor connects directly to the DRAM PHY, bypassing the DRAM controller, as explained in [Architecture](#).

4.1.1 Changing payload memory size

Payload memory size can be changed. Of course it can't exceed the memory available on the hardware platform used. Currently, the payload memory size is defined in [common.py](#), as an argument to LiteX:

```
add_argument("--payload-size", default="1024", help="Payload memory size in bytes  
↔")
```

The examples shown in this chapter don't require any changes. When writing your own [Configurations](#), you may need to change the default value.

4.2 Row mapping

In the case of DRAM modules, the physical layout of the memory rows in hardware can be different from the logical numbers assigned to them. The nature of rowhammer attack is that only the physically adjacent rows are affected by the aggressor row. To deal with the problem of disparity between physical location and logical enumeration, we various mapping strategies can be implemented:

- `TrivialRowMapping` - logical address is the same as physical one
- `TypeARowMapping` - more complex mapping method, reverse-engineered as a part of [this research](#)

- TypeBRowMapping - logical address is the physical one multiplied by 2, taken from [this paper](#)

4.3 Row Generator class

Row Generator class is responsible for creating a list of row numbers used in a rowhammer attack. Currently, only one instance of this class is available.

4.3.1 EvenRowGenerator

Generates a list of even numbered rows. Uses the row mapping specified by the *Payload generator class* used. Two configuration parameters are needed for EvenRowGenerator:

- nr_rows - number of rows to be generated
- max_row - maximal number to be used. The chosen numbers will be *modulo max_row*

4.3.2 HalfDoubleRowGenerator

Generates a list of rows for a **Half-Double** attack. The list will repeat rows to create weight difference between attacks at different distances. Used by HalfDoubleAnalysisPayloadGenerator.

- nr_rows - number of rows in the attack pattern.
- distance_one - does the attack have a distance one component?
- double_sided - is the attack double-sided?
- distance_two - does the attack have a distance two component?
- attack_rows_start - the index of the first attack row.
- max_attack_row_idx - the position of the last attack row relative to attack_rows_start.
- decoy_rows_start - the index of the first decoy row. There are 3 decoy rows that are used as placebos in various situations: to hammer away from the victim but to keep the number of hammers and timing constant.

4.4 Payload generator class

The purpose of the payload generator is to prepare a payload and process the test outcome. It is a class that can be reused in different tests *Configurations*. Payload generators are located in [payload_generators directory](#)

4.4.1 Available payload generators

Row mapping and row generator settings are combined into a payload generator class. Currently, only two payload generators are available.

RowListPayloadGenerator

RowListPayloadGenerator is a simple payload generator that can use a RowGenerator class to generate rows, and then generate a payload that hammers that list of rows (hammering is a term used to describe multiple read operations on the same row). It can also issue refresh commands to the DRAM module. Here are the configs that can be used in `payload_generator_config` for this payload generator:

- `row_mapping` - this is the *Row mapping* used
- `row_generator` - this is the *Row Generator class* used to generate the rows
- `row_generator_config` - parameters for the row generator
- `verbose` - should verbose output be generated (true or false)
- `fill_local` - when enabled, permits shrinking the filled memory area to just the aggressors and the victim
- `read_count` - number of hammers (reads) per row
- `refresh` - should refresh be enabled (true or false)

Example *Configurations* for this test were provided as `configs/example_row_list_*.cfg` files. Some of them require a significant amount of memory declared as payload memory. To execute a minimalistic example from within rowhammer-tester repo, enter:

```
source venv/bin/activate
export TARGET=arty # change accordingly
cd rowhammer_tester/scripts/playbook/
python playbook.py configs/example_row_list_minimal.cfg
```

Expected output:

```
Progress: [=====] 65536 / 65536
Row sequence:
[0, 2, 4, 6, 14, 12, 10, 8, 16, 18]
Generating payload:
  tRAS = 5
  tRP = 3
  tREFI = 782
  tRFC = 32
Repeatabl unit: 930
Repetitions: 93
Payload size = 0.10KB / 1.00KB
Payload per-row toggle count = 0.010K x10 rows
Payload refreshes (if enabled) = 10 (disabled)
Expected execution time = 1903 cycles = 0.019 ms
```

(continues on next page)

(continued from previous page)

...
```

HammerTolerancePayloadGenerator

HammerTolerancePayloadGenerator is a payload generator for measuring and characterizing rowhammer tolerance. It can provide information about how many rows and bits are susceptible to the rowhammer attack. It can also provide information about where the susceptible bits are located.

A series of double-sided hammers against the available group of victim rows is performed. The double-sided hammers increase in intensity based on `read_count_step` parameter. Here are the parameters that can be specified in `payload_generator_config` for this payload generator:

- `row_mapping` - this is the *Row mapping* used
- `row_generator` - this is the *Row Generator class* used to generate the rows
- `row_generator_config` - parameters for the row generator
- `verbose` - should verbose output be generated (true or false)
- `fill_local` - when enabled, permits shrinking the filled memory area to just the aggressors and the victim
- `nr_rows` - number of rows to conduct the experiment over. This is the number of aggressor rows. Victim rows will be 2 times fewer than this number. For example, to perform hammering for 32 victim rows, use 34 as the parameter value
- `read_count_step` - this is how much to increment the hammer count between multiple tests for the same row. This is the number of hammers on single side (total number of hammers on both sides is 2x this value)
- `initial_read_count` - hammer count for the first test for a given row. Defaults to `read_count_step` if unspecified.
- `distance` - distance between aggressors and victim. Defaults to 1.
- `baseline` - when enabled, a retention effect baseline is collected by hammering distant rows for the same amount of time that the aggressors would be hammered.
- `first_dummy_row` - location of the first of two dummy rows used for baselining.
- `iters_per_row` - number of times the hammer count is incremented for each row

The results are a series of histograms with appropriate labeling.

Example *Configurations* for this test were provided as `configs/example_hammer_*.cfg` files. Some of them require a significant amount of memory declared as payload memory. To execute a minimalistic example from within rowhammer-tester repo, enter:

```
source venv/bin/activate
export TARGET=arty # change accordingly
cd rowhammer_tester/scripts/playbook/
python playbook.py configs/example_hammer_minimal.cfg
```

Expected output:

```
Progress: [=====] 3072 / 3072

  tRAS = 5
  tRP = 3
  tREFI = 782
  tRFC = 32
  Repeatable unit: 186
  Repetitions: 93
  Payload size = 0.04KB / 1.00KB
  Payload per-row toggle count = 0.010K x2 rows
  Payload refreshes (if enabled) = 10 (disabled)
  Expected execution time = 1263 cycles = 0.013 ms

Transferring the payload ...

Executing ...
Time taken: 0.647 ms

Progress: [===== ] 323 / 1024 (Errors: 320)
...
```

HalfDoubleAnalysisPayloadGenerator

Half-Double is a Rowhammer phenomenon where accesses to both distance-one and distance-two neighbours of a victim row are used to generate bit flips. This payload generator allows us to characterize the Half-Double effect on a memory part.

For each candidate victim row, the analysis starts out with the maximum number of hammers and minimum dilution level. Then, we proceed as follows:

1. Dilution is increased until pure distance-one attacks stop working.
2. Verify that pure distance-two attack doesn't work.
3. Increase dilution level and record the number of bit flips in the victim until either the bit flips stop or maximum dilution level is reached.
4. Once maximum dilution level is reached or bit flips stop, reduce hammer count by step and reset dilution to initial level and retry step 3. Repeat until the lowest hammer count is reached.

Note: the hammer count changes on a linear scale and dilution changes on an exponential scale.

Results are presented as a table of values with columns representing hammer count and the rows representing dilution levels. See Tables 2 and 3 in the Half-Double white paper as examples.

- `max_total_read_count` - maximum number of hammers issued to any given row during an iteration.
- `read_count_steps` - the amount to decrement the number of hammers for each iteration of the outer loop.
- `initial_dilution` - initial value for dilution. Dilution resets to this value at the beginning of the inner loop.
- `dilution_multiplier` - dilution is multiplied by this value for each iteration of the inner loop.
- `verbose` - generates more output.
- `row_mapping` - specifies the style in which the rows are mapped on the chip.
- `attack_rows_start` - starting row number for rows actually used to attack the victim.
- `max_attack_row_idx` - index measured from `attack_rows_start` for the last attack row.
- `decoy_rows_start` - the position of the first decoy row. There are three decoy rows. They are used as placebos during pure distance one portions of the experiment to make the number of hammers and their timing comparable.
- `max_dilution` - maximum value for dilution.
- `fill_local` - only reinitialize affected rows between experiments, as an optimization.

4.5 Configurations

Test configuration files are represented as JSON files. An example:

```
{
  "inversion_divisor" : 2,
  "inversion_mask" : "0b10",
  "payload_generator" : "RowListPayloadGenerator",
  "payload_generator_config" : {
    "row_mapping" : "TypeARowMapping",
    "row_generator" : "EvenRowGenerator",
    "read_count" : 27,
    "max_iteration" : 10,
    "verbose" : true,
    "refresh" : false,
    "fill_local" : true,
    "row_generator_config" : {
      "nr_rows" : 10,
      "max_row" : 64
    }
  }
}
```

Different parameters are supported:

- `payload_generator` - name of the *Payload generator class* to use
- `row_pattern` - pattern that will be stored in rows

- `inversion_divisor` and `inversion_mask` - controls which rows get the inverted pattern described in *Inversion*
- `payload_generator_config` - these parameters are specific for *Payload generator class* used

4.5.1 Inversion

If needed, the data pattern used for some of the tested rows can be bitwise-inverted.

Two parameters are used to specify which rows are to be inverted:

- `inversion_divisor`
- `inversion_mask`

An example. `inversion_divisor = 8`, `inversion_mask = 0b10010010` (bits 1, 4 and 7 are “on”). We iterate through all row numbers 0,1,2,3,4,...,8,9,10,... First, a modulo `inversion_divisor` operation is performed on a row number. In our case it’s mod 8. Next, we check if the bit in `inversion_mask` in the position corresponding to our row number (after modulo) is “on” or “off”. If it’s “on”, this whole row will be inverted. The results for our example are shown in a table below.

Table 4.1: Inversion example

Row number	Row number modulo divisor (8)	Value
0	0	pattern
1	1	inverted pattern
2	2	pattern
3	3	pattern
4	4	inverted pattern
5	5	pattern
6	6	pattern
7	7	inverted pattern
8	0	pattern
9	1	inverted pattern
10	2	pattern
11	3	pattern
12	4	inverted pattern

DRAM MODULES

When building one of the targets in `rowhammer_tester/targets`, a custom DRAM module can be specified using the `--module` argument. To find the default modules for each target, check the output of `--help`.

Note: Specifying different DRAM module makes most sense on boards that allow to easily replace the DRAM module, such as on ZCU104. On other boards it would be necessary to desolder the DRAM chip and solder a new one.

5.1 Adding new modules

LiteDRAM controller provides out-of-the-box support for many DRAM modules. Supported modules can be found in `litedram/modules.py`. If a module is not listed there, you can add a new definition.

To make development more convenient, modules can be added in the `rowhammer-tester` repository directly in file `rowhammer_tester/targets/modules.py`. These definitions will be used before definitions in LiteDRAM.

Note: After ensuring that the module works correctly, a Pull Request to LiteDRAM should be created to add support for the module.

To add a new module definition, use the existing ones as a reference. New module class should derive from `SDRAMModule` (or the helper classes, e.g. `DDR4Module`). Timing/geometry values for a module have to be obtained from the relevant DRAM module's datasheet. The timings in classes deriving from `SDRAMModule` are specified in nanoseconds. The timing value can also be specified as a 2-element tuple `(ck, ns)`, in which case `ck` is the number of clock cycles and `ns` is the number of nanoseconds (and can be `None`). The highest of the resulting timing values will be used.

5.2 SPD EEPROM

On boards that use DIMM/SO-DIMM modules (e.g. ZCU104) it is possible to read the contents of the DRAM modules's **SPD EEPROM memory**. SPD contains several essential module parameters that the memory controller needs in order to use the DRAM module. SPD EEPROM can be read over I2C bus.

5.2.1 Reading SPD EEPROM

To read the SPD memory use the script `rowhammer_tester/scripts/spd_eeprom.py`. First prepare the environment as described in *Controlling the board*. Then use the following command to read the contents of SPD EEPROM and save it to a file, for example:

```
python rowhammer_tester/scripts/spd_eeprom.py read MTA4ATF51264HZ-3G2J1.bin
```

The contents of the file can then be used to get DRAM module parameters. Use the following command to examine the parameters:

```
python rowhammer_tester/scripts/spd_eeprom.py show MTA4ATF51264HZ-3G2J1.bin 125e6
```

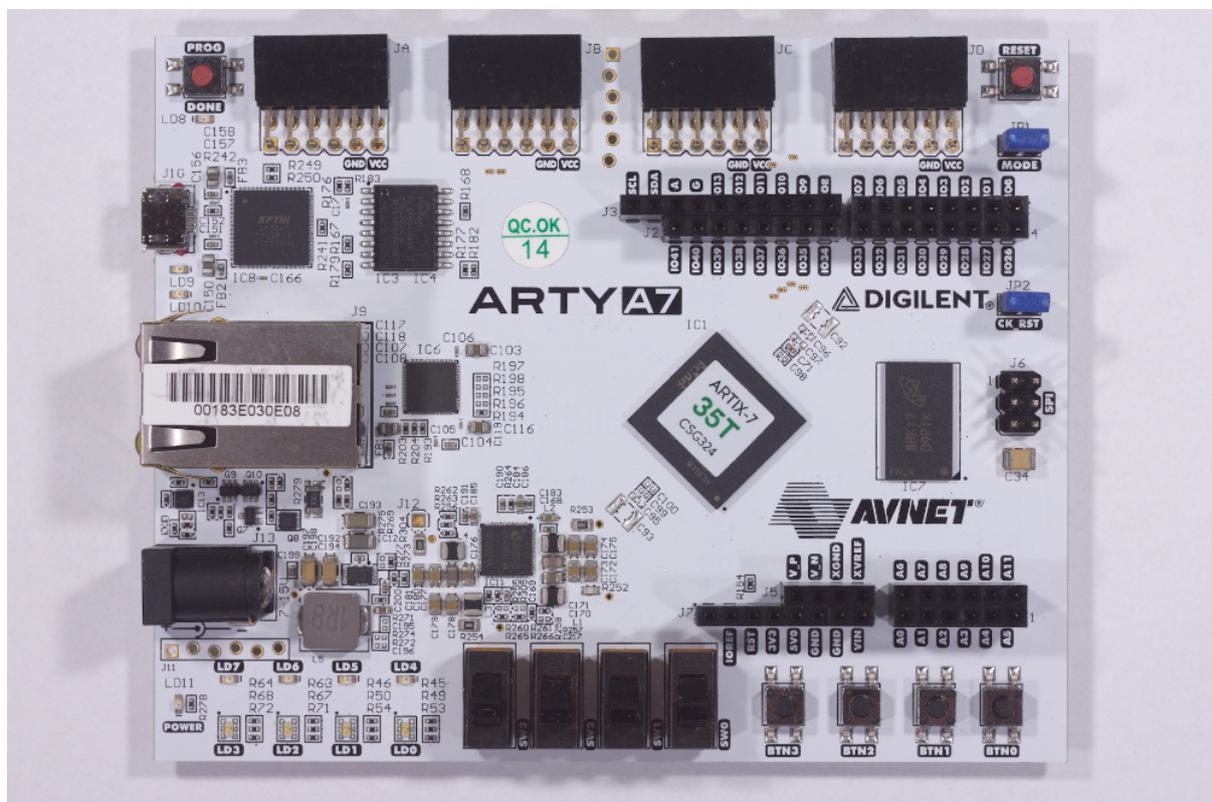

Note that system clock frequency must be passed as an argument to determine timing values in controller clock cycles.

5.2.2 Using SPD data

The memory controller is able to set the timings read from an SPD EEPROM during system boot. The only requirement here is that the SoC is built with I2C controller, and I2C pins are routed to the (R)DIMM module. There is no additional action required from system user. The timings will be set automatically.

ARTY-A7 BOARD

The **Arty-A7 board** allows testing its on-board DDR3 module. The board is designed around the Artix-7™ Field Programmable Gate Array (FPGA) from Xilinx.

The following instructions explain how to set up the board.

6.1 Board configuration

Connect the board USB and Ethernet cables to your computer and configure the network. The board's IP address will be 192.168.100.50 (so you could e.g. use 192.168.100.2/24). The IP_ADDRESS environment variable can be used to modify the board's address. Next, generate the FPGA bitstream:

```
export TARGET=arty
make build
```

Note: This will by default target Arty A7 with the XC7A35TICSG324-1L FPGA. To build for XC7A100TICSG324-1, use `make build TARGET_ARGS="--variant a7-100"`

The results will be located in: `build/arty/gateway/digilent_arty.bit`. To upload it, use:

```
export TARGET=arty
make upload
```

Note: By typing `make` (without `build`) LiteX will generate build files without invoking Vivado.

To save bitstream in flash memory, use:

```
export TARGET=arty
make flash
```

Bitstream will be loaded from flash memory upon device power-on or after a PROG button press.

ZCU104 BOARD

The **ZCU104 board** enables testing DDR4 SO-DIMM modules. It features a Zynq UltraScale+ MPSoC device consisting of PS (Processing System with quad-core ARM Cortex-A53) and PL (programmable logic).

On the ZCU104 board the Ethernet PHY is connected to PS instead of PL. For this reason it is necessary to route the Ethernet/EtherBone traffic through PC <-> PS <-> PL. To do this, a simple EtherBone server has been implemented (the source code can be found in the `firmware/zcu104/etherbone/` directory).

The following instructions show how to set up the board for the first time.

7.1 Board configuration

To make the ZCU104 boot from the SD card it is necessary to ensure proper switch configuration. The mode switch (SW6) consisting of 4 switches is located near the FMC LPC Connector (J5) (the same side of the board as USB, HDMI, Ethernet). For details, see “ZCU104 Evaluation Board User Guide (UG1267)”. To use an SD card, configure the switches as follows:

1. ON
2. OFF
3. OFF
4. OFF

7.2 Preparing SD card

For easiest setup, get the pre-built SD card image `zcu104.img` from [github releases](#). It has to be loaded to the microSD card. To load it to the SD card, insert the card into your PC card slot and find the device name. `lsblk` can be used to check available devices. Example output can look like:

```
$ lsblk
NAME        MAJ:MIN RM   SIZE RO TYPE MOUNTPOINT
sda          8:0    0 931.5G  0 disk
└─sda1       8:1    0 931.5G  0 part /data
sdb          8:16    1  14.8G  0 disk
└─sdb1       8:17    1   128M  0 part /run/media/BOOT
```

(continues on next page)

(continued from previous page)

```
└─sdb2      8:18   1  128M  0 part /run/media/rootfs
nvme0n1     259:0   0 476.9G  0 disk
├─nvme0n1p1 259:1   0  512M  0 part /boot
└─nvme0n1p2 259:2   0 476.4G  0 part /
```

In the example output the SD card is sdb with two partitions sdb1 and sdb2.

Warning: Make sure that you have selected the proper device name or you may damage the hard drive on your system! Check the device SIZE to match the size of your microSD card and compare the outputs of the `lsblk` command with and without the SD card inserted.

Make sure to unmount all partitions on the card before loading the image. For example, assuming the SD card is `/dev/sdb` (device is without a number), use `sudo umount /dev/sdb1 /dev/sdb2` to unmount its partitions.

To load the image, use the following command, replacing `<DEVICE>` according to the output of `lsblk` (in the example above it would be `/dev/sdb`):

```
sudo dd status=progress oflag=sync bs=4M if=zcu104.img of=<DEVICE>
```

Now, the microSD card should be ready to use. If it has been loaded successfully, you should be able to mount the two partitions (BOOT and rootfs) on your PC and browse the files. First, check if your system hasn't auto-mounted the partitions. If not, then you can for example use:

```
sudo mkdir -p /mnt/boot /mnt/rootfs
sudo mount /dev/sdb1 /mnt/boot
sudo mount /dev/sdb2 /mnt/rootfs
```

7.3 Loading bitstream

Instead of loading the bitstream through the JTAG interface, it must be copied to the microSD card BOOT partition (FAT32). The bitstream will be then loaded by the bootloader during system startup.

The prebuilt card image comes with a sample bitstream, but in order to use the provided rowhammer Python scripts, a fresh bitstream must be created. Build the bitstream as you would do for other boards:

```
export TARGET=zcu104
export IP_ADDRESS=... # optional
make build
```

Note: You only need to export `IP_ADDRESS` if you want to use a different address than the default one (see [Network setup](#)).

The resulting bitstream file will be located in `build/zcu104/gateway/zcu104.bit`. Copy it to the BOOT partition (FAT32) of the microSD card. Make sure it is named `zcu104.bit`.

When the SD card is ready, insert it into the microSD card slot on your ZCU104 board and power it on.

7.4 Verifying if bitstream is loaded

The first indication that the bitstream has been loaded successfully are the onboard LEDs. When the board is powered up, the LED will be red, which then turns green if the bitstream is loaded successfully. The ZCU104 bitstream will also make the four LEDs near the user buttons turn on and off in a circular pattern.

Fig. 7.1: The board without a bitstream.

Fig. 7.2: The state when the bitstream has been loaded successfully.

The serial console over USB can be used to further check if the board is working correctly.

7.5 ZCU104 microUSB

ZCU104 has a microUSB port connected to the FTDI chip. It provides 4 channels, which are connected as follows:

- Channel A is configured to support the JTAG chain.
- Channel B implements UART0 MIO18/19 connections.
- Channel C implements UART1 MIO20/21 connections.
- Channel D implements UART2 PL-side bank 28 4-wire interface.

In general they should show up as subsequent `/dev/ttyUSBx` devices (0-3 if no others were present). Channel B is connected to the console in the PS Linux system.

To login to the board connect the microUSB cable to the PC and find Channel B among the `ttyUSB` devices in your system. If there are only `ttyUSB0` to `ttyUSB3` then Channel B will be `ttyUSB1`.

Then use e.g. `picocom` or `minicom` to open the serial console. Install one of them if not already installed on your system. With `picocom` use the following command (may require `sudo`):

```
picocom -b 115200 /dev/ttyUSB1
```

Then press enter, and when you see the following prompt,

```
Welcome to Buildroot
buildroot login:
```

use `login root` and empty password. You can set up a password if needed.

7.6 Network setup

Connect the ZCU104 board to your local network (or directly to a PC) using an Ethernet cable.

The board uses a static IP address. By default it will be `192.168.100.50`. If it does not conflict with your local network configuration you can skip this section. (the default configuration can be found [here](#)).

To verify connectivity, use `ping 192.168.100.50`. You should see data being transmitted, e.g.

```
$ ping 192.168.100.50
PING 192.168.100.50 (192.168.100.50) 56(84) bytes of data.
64 bytes from 192.168.100.50: icmp_seq=1 ttl=64 time=0.332 ms
64 bytes from 192.168.100.50: icmp_seq=2 ttl=64 time=0.072 ms
64 bytes from 192.168.100.50: icmp_seq=3 ttl=64 time=0.081 ms
```

7.6.1 Modifying network configuration

If you need to modify the configuration, edit file `/etc/network/interfaces`. The Linux rootfs on the SD card is fairly minimal, so there is only the `vi` editor available. You could also just mount the card on your PC and edit the file.

After changing the configuration, reboot the board (type `reboot` in the serial console) and test if you can ping it with `ping <NEW_IP_ADDRESS>`.

7.7 SSH access

These instructions are optional but can be useful for more convenient updates of the bitstream (no need to remove the SD card from the slot on ZCU104).

Note: SSH on the board is configured to allow passwordless root access for simplicity but if that poses a security risk, modify `/etc/ssh/sshd_config` according to your needs and add a password for root.

You can login over SSH using (replace the IP address if you modified board network configuration):

```
ssh root@192.168.100.50
```

To access the boot partition, first mount it with:

```
mount /dev/mmcblk0p1 /boot
```

This can be automated by adding the following entry in `/etc/fstab`:

```
/dev/mmcblk0p1 /boot          vfat    rw           0           2
```

When the boot partition is mounted, you can use `scp` to load the new bitstream, e.g.

```
scp build/zcu104/gateway/zcu104.bit root@192.168.100.50:/boot/zcu104.bit
```

Then use the `reboot` command to restart the board.

7.8 Controlling the board

When the setup has been finished the board can be controlled as any other board. Just make sure to use `export TARGET=zcu104` before using the scripts (and `export IP_ADDRESS=...` if you modified the network configuration).

7.9 ZCU104 SD card image

The easiest way is to use the prebuilt SD card image, as described in *Preparing SD card* section. However, it is possible to build the image from source, if needed.

The SD card image consists of boot partition and rootfs. Currently, only rootfs is built using buildroot. The boot partition content has to be built manually.

In the future, the buildroot configuration should be revised to build all the required software. Initial configuration has been included but it is still a work in progress and does not boot.

7.9.1 Bootloaders & kernel

Currently, we are using Xilinx FSBL, but it should be possible to use U-Boot SPL ([link1](#), [link2](#)).

FSBL and PMU firmware can be built with following the steps:

- <https://xilinx-wiki.atlassian.net/wiki/spaces/A/pages/18842462/Build+PMU+Firmware>
- <https://xilinx-wiki.atlassian.net/wiki/spaces/A/pages/18841798/Build+FSBL>

Create a project from the Vivado example project “Base Zynq UltraScale+ MPSoC” for ZCU104 eval board. Open the PS IP configurator and add the following: * PS-PL Interfaces -> AXI HPM0 FPD (32-bit), AXI HPM1 FPD (32-bit) * disable Carrier Detect in Memory Interfaces -> SD -> SD 0

The following script can be used to generate FSBL, PMU firmware and Device Tree:

```
#!/usr/bin/tclsh

set hwdsgn [open_hw_design PATH/T0/Base_Zynq_MPSoC_wrapper.hdf]

generate_app -hw $hwdsgn -os standalone -proc psu_cortexa53_0 -app zynqmp_fsbl -
↳ compile -sw fsbl -dir ./fsbl/
generate_app -hw $hwdsgn -os standalone -proc psu_pmu_0 -app zynqmp_pmufw -
↳ compile -sw pmufw -dir ./pmufw

set_repo_path PATH/T0/device-tree-xlnx
create_sw_design device-tree -os device_tree -proc psu_cortexa53_0
generate_target -dir dts

close_hw_design [current_hw_design]
```

The Device Tree generated by Vivado is missing the ethernet-phy node. Modify `pcw.dtsi` as follows:

```
&gem3 {
    phy-mode = "rgmii-id";
    status = "okay";
    xlnx,ptp-enet-clock = <0x0>;
    phy0: phy@c {
```

(continues on next page)

(continued from previous page)

```
    reg = <0xc>;
    ti,rx-internal-delay = <0x8>;
    ti,tx-internal-delay = <0xa>;
    ti,fifo-depth = <0x1>;
    ti,rxctrl-strap-worka;
};
};
```

Then generate the Device Tree Blob in the dts directory:

```
gcc -I include -I . -E -nostdinc -undef -D__DTS__ -x assembler-with-cpp -o system.
↪dts system-top.dts
dtc -I dts -O dtb -o system.dtb system.dts
```

Build the rest of the required components:

- ARM trusted firmware: (<https://github.com/Xilinx/arm-trusted-firmware.git>) e6eea88b14aaf456c49f9c7e6747584224648cb9 (tag: xlnx_rebase_v2.2)
- U-Boot: (<https://github.com/Xilinx/u-boot-xlnx.git>) d8fc4b3b70bccf1577dab69f6ddfd4ada9a93bac (tag: xilinx-v2018.3)
- Linux kernel: (<https://github.com/Xilinx/linux-xlnx.git>) 22b71b41620dac13c69267d2b7898ebfb14c954e (tag: xlnx_rebase_v5.4_2020.1)

Note: It may be necessary to apply the patches from firmware/zcu104/buildroot/board/zynqmp/patches when building U-Boot/Linux.

When building U-Boot make sure to update its configuration (u-boot-xlnx/.config) with the following options:

```
CONFIG_USE_BOOTARGS=y
CONFIG_BOOTARGS="earlycon clk_ignore_unused console=ttyPS0,115200 root=/dev/
↪mmcbk0p2 rootwait rw earlyprintk rootfstype=ext4"
CONFIG_USE_BOOTCOMMAND=y
CONFIG_BOOTCOMMAND="load mmc 0:1 0x2000000 zcu104.bit; fpga load 0 0x2000000
↪$filesize; load mmc 0:1 0x2000000 system.dtb; load mmc 0:1 0x3000000 Image;_
↪booti 0x3000000 - 0x2000000"
```

These configure U-Boot to load the bitstream from the SD card and then start the system. Unfolding CONFIG_BOOTCOMMAND we can see:

```
load mmc 0:1 0x2000000 zcu104.bit
fpga load 0 0x2000000 $filesize
load mmc 0:1 0x2000000 system.dtb
load mmc 0:1 0x3000000 Image
booti 0x3000000 - 0x2000000
```

Example of building ARM Trusted firmware:

```
make distclean
make -j`nproc` PLAT=zynqmp RESET_TO_BL31=1
```

Example of building U-Boot:

```
make -j`nproc` distclean
make xilinx_zynqmp_zcu104_revC_defconfig
# now modify .config directly or using `make menuconfig` as described earlier
make -j`nproc`
```

Example of building Linux:

```
make -j`nproc` ARCH=arm64 distclean
make ARCH=arm64 xilinx_zynqmp_defconfig
# optional `make menuconfig`
make -j`nproc` ARCH=arm64 dtbs
make -j`nproc` ARCH=arm64
```

Then download [zynq-mkbootimage](#) and prepare the following boot.bif file:

```
image:
{
  [fsbl_config] a53_x64
  [bootloader] fsbl.elf
  [pmufw_image] pmufw.elf
  [, destination_cpu=a53-0, exception_level=e1-2] bl31.elf
  [, destination_cpu=a53-0, exception_level=e1-2] u-boot.elf
}
```

Open a terminal and make sure that the filepaths specified in boot.bif are correct. Then use ``mkbootimage -zynqmp boot.bif boot.bin`` to create the boot.bin file.

7.9.2 Root filesystem

Download buildroot

```
git clone git://git.buildroot.net/buildroot
git checkout 2020.08.2
```

Note: As of time of writing git checkout f45925a951318e9e53bead80b363e004301adc6f was required to avoid fakeroot errors when building.

Then prepare configuration using external sources and build everything:

```
make BR2_EXTERNAL=/PATH/TO/REPO/rowhammer-tester/firmware/zcu104/buildroot zynqmp_
↪zcu104_defconfig
make -j`nproc`
```

7.9.3 Flashing SD card

One can use `fdisk` to directly partition the SD card `/dev/xxx` or use the provided `genimage` configuration to create an SD card image that can be then directly copied to the SD card. The second method is usually more convenient.

Formatting SD card manually

Use `fdisk` or other tool to partition the SD card. The recommended partitioning scheme is as follows:

- Partition 1, FAT32, 128M
- Partition 2, ext4, 128M

Then create the filesystems:

```
sudo mkfs.fat -F 32 -n BOOT /dev/OUR_SD_CARD_PARTITION_1
sudo mkfs.ext4 -L rootfs /dev/OUR_SD_CARD_PARTITION_2
```

Write the rootfs:

```
sudo dd status=progress oflag=sync bs=4M if=/PATH/TO/BUILDROOT/output/images/
↪rootfs.ext4 of=/dev/OUR_SD_CARD_PARTITION_2
```

Mount the boot partition and copy the boot files and kernel image created earlier and the ZCU104 bitstream:

```
cp boot.bin /MOUNT/POINT/BOOT/
cp /PATH/TO/rowhammer-tester/build/zcu104/gateway/zcu104.bit /MOUNT/POINT/BOOT/
cp /PATH/TO/linux-xlnx/arch/arm64/boot/Image /MOUNT/POINT/BOOT/
cp /PATH/TO/linux-xlnx/arch/arm64/boot/dts/xilinx/zynqmp-zcu104-revA.dtb /MOUNT/
↪POINT/BOOT/system.dtb
```

Note: make sure to name the device tree blob `system.dtb` for the U-Boot to be able to find it (as shown in above commands).

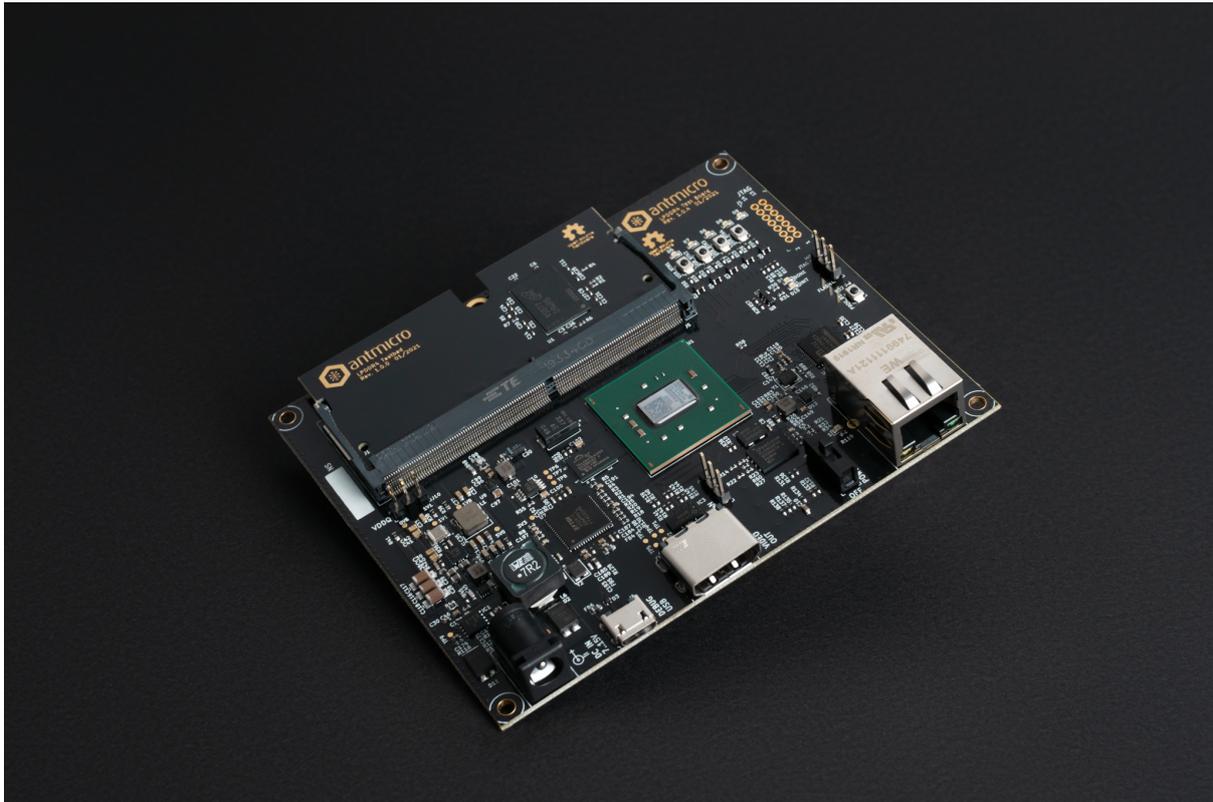

Using genimage

By default ZCU104 buildroot configuration will also build the `genimage` tool for the host system. Image configuration is described in the `firmware/zcu104/image.cfg` file. There is also a script `firmware/zcu104/genimage.sh` for convenience. Run it without arguments to get help. Then run it providing correct paths to all the required files to generate the `zcu104.img` file.

The image can be then copied to the SD card device (not partition! so e.g. `/dev/sdb`, not `/dev/sdb1`) using `dd`:

```
sudo dd status=progress oflag=sync bs=4M if=/PATH/TO/zcu104.img of=/dev/OUR_SD_
↪CARD
```

LPDDR4 TEST BOARD

LPDDR4 Test Board is a platform developed by Antmicro for testing LPDDR4 memory. It uses Xilinx Kintex-7 FPGA (XC7K70T-FBG484) and by default includes a custom SO-DIMM module with Micron's MT53E256M16D1 LPDDR4 DRAM.

The hardware is open and can be found on GitHub:

- Test board: <https://github.com/antmicro/lpddr4-test-board>
- Testbed: <https://github.com/antmicro/lpddr4-testbed>

8.1 Board configuration

First insert the LPDDR4 DRAM module into the socket and make sure that jumpers are set in correct positions:

- VDDQ (J10) should be set in position 1V1
- MODE2 should be set in position FLASH

Then connect the board USB and Ethernet cables to your computer and configure the network. The board's IP address will be 192.168.100.50 (so you could e.g. use 192.168.100.2/24). The IP_ADDRESS environment variable can be used to modify the board's address. Next, generate the FPGA bitstream:

```
export TARGET=lpddr4_test_board
make build
```

The results will be located in: build/lpddr4_test_board/gateway/antmicro_lpddr4_test_board.bit. To upload it, use:

```
export TARGET=lpddr4_test_board
make upload
```

Note: By typing make (without build) LiteX will generate build files without invoking Vivado.

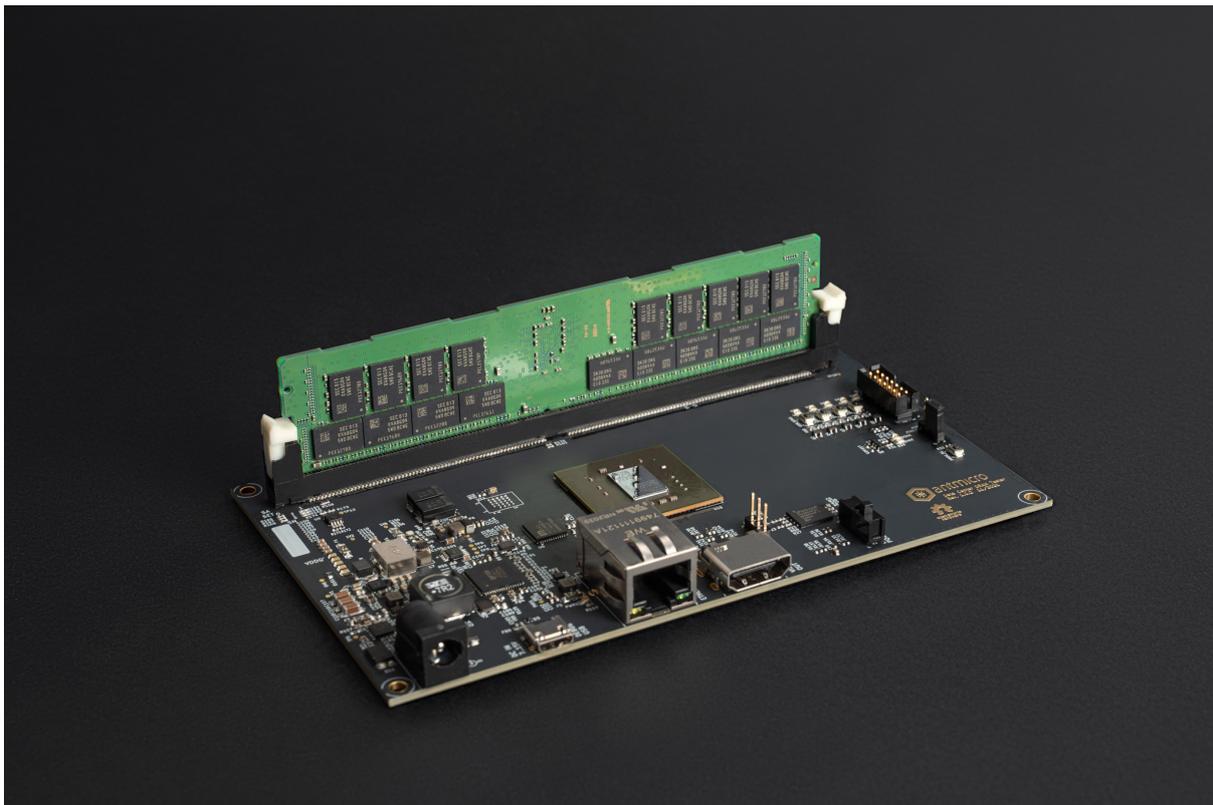

To save bitstream in flash memory, use:

```
export TARGET=lpddr4_test_board
make flash
```

Warning: There is a JTAG/FLASH jumper named MODE2 on the right side of the board. Unless it's set to the FLASH setting, the FPGA will load the bitstream received via JTAG.

Bitstream will be loaded from flash memory upon device power-on or after a PROG button press.

DATA CENTER DRAM TESTER

The data center DRAM tester is an open source hardware test platform that enables testing and experimenting with various DDR4 RDIMMs (Registered Dual In-Line Memory Module).

The hardware is open and can be found on GitHub: <https://github.com/antmicro/data-center-dram-tester/>

The following instructions explain how to set up the board.

9.1 Board configuration

First connect the board USB and Ethernet cables to your computer, plug the board to the socket and turn it on using power switch. Then configure the network. The board's IP address will be 192.168.100.50 (so you could e.g. use 192.168.100.2/24). The IP_ADDRESS environment variable can be used to modify the board's address. Next, generate the FPGA bitstream:

```
export TARGET=ddr4_datacenter_test_board
make build
```

Note: By typing make (without build) LiteX will generate build files without invoking Vivado.

The results will be located in: build/ddr4_datacenter_test_board/gateway/antmicro_datacenter_ddr4_test_board.bit. To upload it, use:

```
export TARGET=ddr4_datacenter_test_board
make upload
```

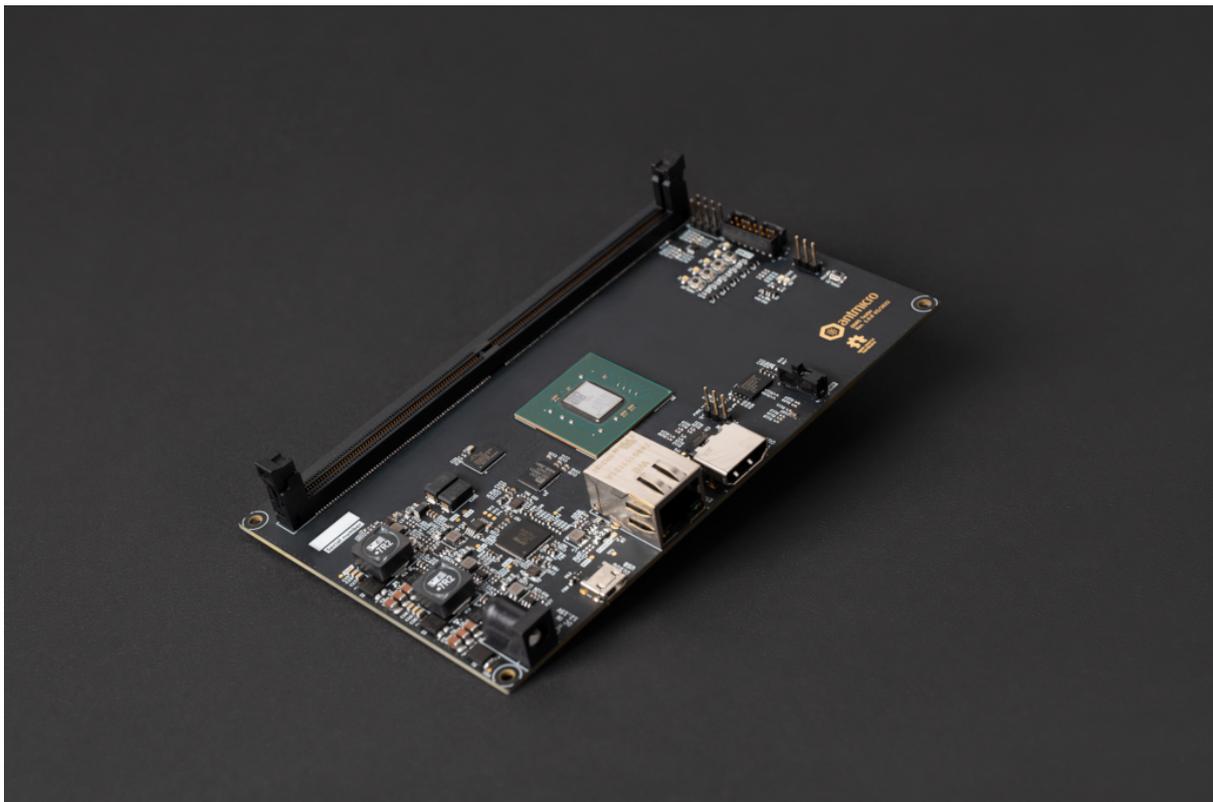

To save bitstream in flash memory, use:

```
export TARGET=ddr4_datacenter_test_board
make flash
```

Warning: There is a JTAG/SPI jumper named MODE2 on the right side of the board. Unless it's set to the SPI setting, the FPGA will load the bitstream received via JTAG.

Bitstream will be loaded from flash memory upon device power-on or after a PROG button press.

DDR5 TESTER

The DDR5 tester is an open source hardware test platform that enables testing and experimenting with various DDR5 RDIMMs (Registered Dual In-Line Memory Module).

The hardware is open and can be found on GitHub: <https://github.com/antmicro/ddr5-tester/>

The following instructions explain how to set up the board.

10.1 Rowhammer Tester Target Configuration

First connect the board USB and Ethernet cables to your computer, plug the board to the socket and turn it on using power switch. Then configure the network. The board's IP address will be 192.168.100.50 (so you could e.g. use 192.168.100.2/24). The `IP_ADDRESS` environment variable can be used to modify the board's address. Next, generate the FPGA bitstream:

```
export TARGET=ddr5_tester
make build TARGET_ARGS="--l2-size 256 --build --iodelay-clk-freq 400e6 --bios-lto_
↳--rw-bios --module MTC10F1084S1RC --no-sdram-hw-test"
```

Note: `--l2-size 256` sets L2 cache size to 256 bytes
`--no-sdram-hw-test` disables hw accelerated memory test

Note: By typing `make` (without `build`) LiteX will generate build files without invoking Vivado.

The results will be located in: `build/ddr5_tester/gateway/antmicro_ddr5_tester.bit`. To upload it, use:

```
export TARGET=ddr5_tester
make upload
```

To save bitstream in flash memory, use:

```
export TARGET=ddr5_tester
make flash
```

Warning: There is a JTAG/SPI jumper named MODE on the right side of the board. Unless it's set to the SPI setting, the FPGA will load the bitstream received via JTAG.

Bitstream will be loaded from flash memory upon device power-on or after a PROG button press.

10.2 Linux Target Configuration

There's another DDR5 Tester target provided. The `ddr5_tester_linux` is a linux capable target (**with no rowhammer tester**) that allows you to define custom DDR5 tester module utilizing linux-based software.

10.2.1 Base DDR5 Tester Linux Options

The `ddr5_tester_linux` is configured via specifying `TARGET_ARGS` variable. The required arguments for the `ddr5_tester_linux` are:

Option	Documentation
<code>--build</code>	When specified will invoke synthesis and hardware analysis tool (Vivado by default). Will produce programmable bitstream.
<code>--l2-size</code>	Specifies the L2 cache size.
<code>--iodelay-clk</code>	IODELAY clock frequency.
<code>--module</code>	The DDR5 module to be used.
<code>--with-wishbone</code>	VexRiscV SMP specific option. Disables native LiteDRAM interface.
<code>--wishbone-force</code>	VexRiscV SMP specific option. Forces the wishbone bus to be 32 bits wide.

Additionally, **etherbone** or **ethernet** can be set up with either:

10.2.2 Ethernet Options

Option	Documentation
<code>--with-ethernet</code>	Sets up ethernet for DDR5 Tester board.
<code>--remote-ip-address</code>	The IP address of the remote machine connected to DDR5 Tester.
<code>--local-ip-address</code>	Local (DDR5 Tester's) IP address.

10.2.3 Etherbone Options

Option	Documentation
<code>--with-etherbone</code>	Sets up ethernet for DDR5 Tester board.
<code>--ip-address</code>	IP address to be used for the etherbone.
<code>--mac-address</code>	MAC address to be used for the etherbone.

10.2.4 Building DDR5 Tester Linux Target

After having configured the DDR5 Tester Linux, the target can be build with `make build` Makefile target. Use example of DDR5 Tester Linux Target with ethernet configured:

```
make build TARGET=ddr5_tester_linux TARGET_ARGS="--build --l2-size 256 --iodelay-
↪clk-freq 400e6 --module MTC10F1084S1RC --with-wishbone-memory --wishbone-force-
↪32b --with-ethernet --remote-ip-address 192.168.100.100 --local-ip-address 192.
↪168.100.50"
```

10.2.5 Interacting with DDR5 Tester Linux Target

First, load the bitstream onto the DDR5 Tester with the help of the OpenFPGALoader:

```
openFPGALoader --board antmicro_ddr5_tester build/ddr5_tester_linux/gateway/  
↪antmicro_ddr5_tester.bit --freq 3e6
```

In order to connect to the board, assign IP Address – 192.168.100.100 – to the ethernet interface that is plugged to the DDR5 Tester board and set up the device if needed. For example by:

```
ip addr add 192.168.100.100/24 dev $ETH  
ip link set dev $ETH up
```

Where **ETH** is the name of your ethernet interface.

When the ethernet interface has been set up correctly, you may access the BIOS console on the DDR5 Tester with:

```
picocom -b 115200 /dev/ttyUSB2
```

10.2.6 Setting up TFTP Server

From this this point, several linux boot methods can be invoked but booting via ethernet is recommended. In order to enable netboot, the TFTP server needs to be set up first.

Note: Running TFTP server varies between distributions, this can mean different TFTP implementation name and a different location of the configuration file.

As an example, here's a quick guide on how to configure TFTP server for Arch Linux:

Firstly, if not equipped already, get an implementation of a TFTP server, for example:

```
pacman -S tftp-hpa
```

The TFTP server is configured via a `/etc/conf.d/tftpd` file, here's a suggested configuration for the DDR5 Tester Linux boot process:

```
TFTP_USERNAME="tftp"  
TFTPD_OPTIONS="--secure"  
TFTP_DIRECTORY="/srv/tftp"  
TFTP_ADDRESS="192.168.100.100:69"
```

The **TFTP_ADDRESS** is the specified **–remote-ip-address** whilst building the target and the port is the default one for the TFTP server. The **TFTP_DIRECTORY** is the TFTP's root directory.

Then, the TFTP service needs to be started:

```
systemctl start tftpd
```

To check if the TFTP sever has been set up properly, one may run:

```
cd /srv/tftp/ && echo "TEST TFTP SERVER" > test  
cd ~/ && tftp 192.168.100.100 -c get test
```

The `test` file should appear in the home directory with “TEST TFTP SERVER” contents.

10.2.7 Booting Linux on DDR5 Tester Linux Target

You will need the following binaries:

- Linux kernel Image
- Compiled devicetree
- Opensbi’s `fw_jump.bin`
- `rootfs.cpio`

All of those can be obtained with the use of provided `buildroot_ext` buildroot external configuration. To build binaries with buildroot run:

```
git clone --single-branch -b 2023.05.x https://github.com/buildroot/buildroot.git  
pushd buildroot  
make BR2_EXTERNAL="$(pwd)/../buildroot_ext" ddr5_vexriscv_defconfig
```

Then, transfer the binaries to the TFTP root directory:

```
mv buildroot/output/images/* /srv/tftp/  
mv /srv/tftp/fw_jump.bin /srv/tftp/opensbi.bin
```

The address map of the binaries alongside boot args can be contained within the `boot.json` file, for example:

```
{  
  "/srv/tftp/Image": "0x40000000",  
  "/srv/tftp/rv32.dtb": "0x40ef0000",  
  "/srv/tftp/rootfs.cpio": "0x42000000",  
  "/srv/tftp/opensbi.bin": "0x40f00000",  
  "bootargs": {  
    "r1": "0x00000000",  
    "r2": "0x40ef0000",  
    "r3": "0x00000000",  
    "addr": "0x40f00000"  
  }  
}
```

Having placed linux boot binaries in the TFTP’s root directory with `boot.json`, the netboot can be invoked from BIOS console with:

```
netboot /srv/tftp/boot.json
```

Upon successful execution a similar log will be printed:

```

litex> netboot /srv/tftp/boot.json
Booting from network...
Local IP: 192.168.100.50
Remote IP: 192.168.100.100
Booting from /srv/tftp/boot.json (JSON)...
Copying /srv/tftp/Image to 0x40000000... (7395804 bytes)
Copying /srv/tftp/rv32.dtb to 0x40ef0000... (2463 bytes)
Copying /srv/tftp/rootfs.cpio to 0x42000000... (22128128 bytes)
Copying /srv/tftp/opensbi.bin to 0x40f00000... (1007056 bytes)
Executing booted program at 0x40f00000

----- Liftoff! -----

```

Then, the Opensbi and Linux boot log should follow:

```

OpenSBI v1.3-24-g84c6dc1

DDR5 TEST BOARD

The DDR5 test board is an open source hardware test platform that enables testing and experimenting with various x4/x8 DDR5 modules embedded on DDR5 testbed.

The hardware is open and can be found on GitHub:

- Main board <https://github.com/antmicro/lpddr4-test-board/>
- Testbed <https://github.com/antmicro/ddr5-testbed/>

The following instructions explain how to set up the board.

11.1 Board configuration

First connect the board USB and Ethernet cables to your computer, plug the board to the socket and turn it on using power switch. Then configure the network. The board's IP address will be 192.168.100.50 (so you could e.g. use 192.168.100.2/24). The IP_ADDRESS environment variable can be used to modify the board's address. Next, generate the FPGA bitstream:

```
export TARGET=ddr5_test_board
make build TARGET_ARGS="--l2-size 256 --build --iodelay-clk-freq 400e6 --bios-lto_
↵--rw-bios --no-sdram-hw-test"
```

Note: `-l2-size 256` sets L2 cache size to 256 bytes

`--no-sdram-hw-test` disables hw accelerated memory test

Note: By typing `make` (without `build`) LiteX will generate build files without invoking Vivado.

The results will be located in: `build/ddr5_test_board/gateway/antmicro_ddr5_test_board.bit`. To upload it, use:

```
export TARGET=ddr5_test_board
make upload
```

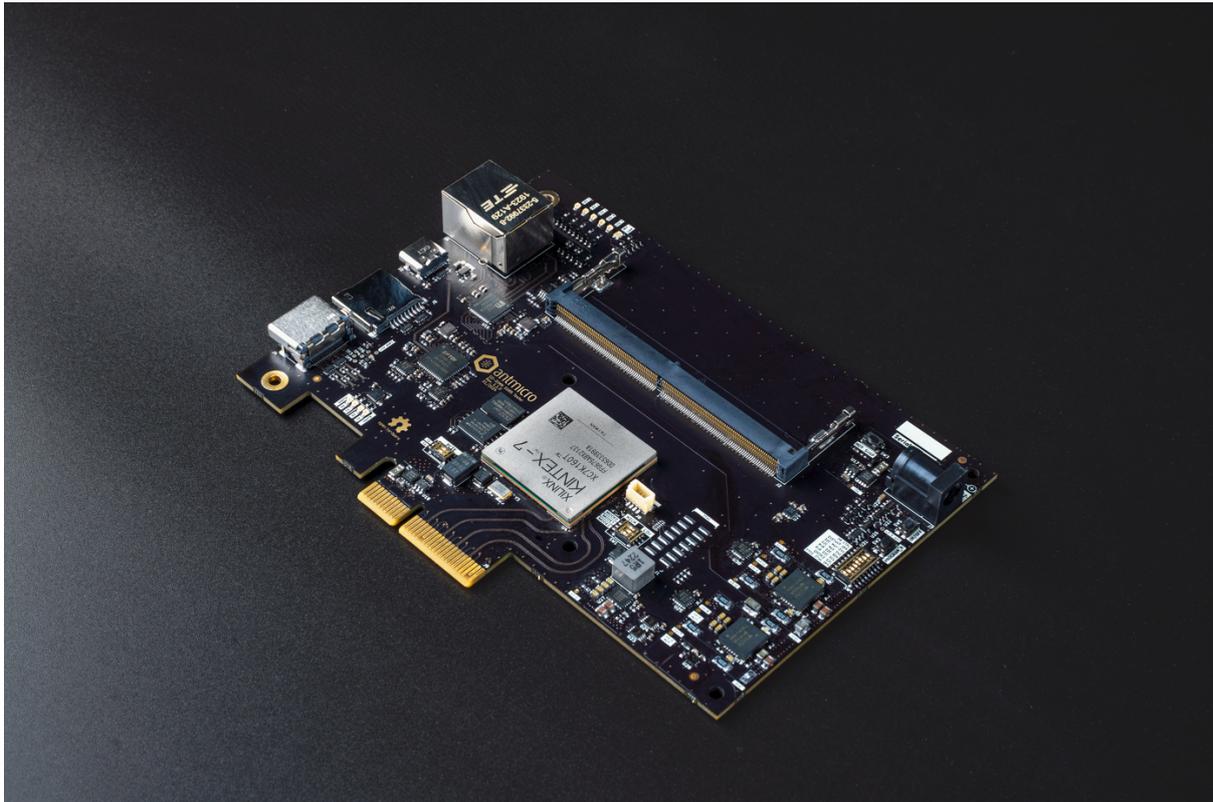

To save bitstream in flash memory, use:

```
export TARGET=ddr5_test_board
make flash
```

Warning: There is a JTAG/SPI jumper named MODE2 on the right side of the board. Unless it's set to the SPI setting, the FPGA will load the bitstream received via JTAG.

Bitstream will be loaded from flash memory upon device power-on or after a PROG button press.

SO-DIMM DDR5 TESTER

The SO-DIMM DDR5 tester is an open source hardware test platform that enables testing and experimenting with various DDR5 SO-DIMM modules and Antmicro LPDDR5 testbed.

The hardware is open and can be found on GitHub: <https://github.com/antmicro/sodimm-ddr5-tester>

12.1 Rowhammer Tester Target Configuration

The following instructions explain how to set up the board.

Connect the board USB-C J3 and Ethernet J6 via cable to your computer, plug the board into the power socket J7 and turn it on using power switch SW5. Then configure the network. The board's IP address will be 192.168.100.50 (so you could e.g. use 192.168.100.2/24). The IP_ADDRESS environment variable can be used to modify the board's address. Next, generate the FPGA bitstream:

```
export TARGET=sodimm_ddr5_tester
make build TARGET_ARGS="--l2-size 256 --build --iodelay-clk-freq 400e6 --bios-lto_
↳--rw-bios --no-sdram-hw-test"
```

Note: `--l2-size 256` sets L2 cache size to 256 bytes

`--no-sdram-hw-test` disables hw accelerated memory test

Note: By typing `make` (without `build`) LiteX will generate build files without invoking Vivado.

The results will be located in: `build/sodimm_ddr5_tester/gateway/antmicro_sodimm_ddr5_tester.bit`. To upload it, use:

```
export TARGET=sodimm_ddr5_tester
make upload
```

To save bitstream in flash memory, use:

```
export TARGET=sodimm_ddr5_tester
make flash
```

Warning: There is a SW1 MODE selector to the right of the FPGA. If the bitstream needs to be loaded from the Flash memory, select Master SPI mode. This configuration is set by default

Configuration mode	MODE[2]	MODE[1]	MODE[0]
Master Serial	0	0	0
Master SPI	0	0	1
Master BPI	0	1	0
Master SelectMAP	1	0	0
JTAG	1	0	1
Slave SelectMAP	1	1	0
Slave Serial	1	1	1

Bitstream will be loaded from flash memory upon device power-on or after a PROG button press.

DOCUMENTATION FOR ROW HAMMER TESTER ARTY-A7

13.1 Modules

13.1.1 Interrupt Controller

This device has an EventManager-based interrupt system. Individual modules generate *events* which are wired into a central interrupt controller.

When an interrupt occurs, you should look the interrupt number up in the CPU- specific interrupt table and then call the relevant module.

Assigned Interrupts

The following interrupts are assigned on this system:

Interrupt	Module
1	<i>TIMERO</i>
0	<i>UART</i>

13.2 Register Groups

13.2.1 LEDS

Register Listing for LEDS

Register	Address
<i>LEDS_OUT</i>	<i>0xf0000000</i>

LEDS_OUT

Address: $0xf0000000 + 0x0 = 0xf0000000$

Led Output(s) Control.

13.2.2 DDRPHY

Register Listing for DDRPHY

Register	Address
<i>DDRPHY_RST</i>	<i>0xf0000800</i>
<i>DDRPHY_DLY_SEL</i>	<i>0xf0000804</i>
<i>DDRPHY_HALF_SYS8X_TAPS</i>	<i>0xf0000808</i>
<i>DDRPHY_WLEVEL_EN</i>	<i>0xf000080c</i>

Address: $0xf0001800 + 0x0 = 0xf0001800$

DDRCTRL_INIT_ERROR

Address: $0xf0001800 + 0x4 = 0xf0001804$

13.2.5 ETHPHY

Register Listing for ETHPHY

Register	Address
<i>ETHPHY_CRG_RESET</i>	<i>0xf0002000</i>
<i>ETHPHY_MDIO_W</i>	<i>0xf0002004</i>
<i>ETHPHY_MDIO_R</i>	<i>0xf0002008</i>

ETHPHY_CRG_RESET

Address: $0xf0002000 + 0x0 = 0xf0002000$

ETHPHY_MDIO_W

Address: $0xf0002000 + 0x4 = 0xf0002004$

Field	Name	Description

ETHPHY_MDIO_R

Address: $0xf0002000 + 0x8 = 0xf0002008$

Field	Name	Description

13.2.6 ROWHAMMER

Row Hammer DMA attacker

This module allows to perform a Row Hammer attack by configuring it with two addresses that map to different rows of a single bank. When enabled, it will perform alternating DMA reads from the given locations, which will result in the DRAM controller having to repeatedly open/close rows at each read access.

Register Listing for ROWHAMMER

Register	Address
<i>ROWHAMMER_ENABLED</i>	<i>0xf0002800</i>
<i>ROWHAMMER_ADDRESS1</i>	<i>0xf0002804</i>
<i>ROWHAMMER_ADDRESS2</i>	<i>0xf0002808</i>
<i>ROWHAMMER_COUNT</i>	<i>0xf000280c</i>

ROWHAMMER_ENABLED

Address: $0xf0002800 + 0x0 = 0xf0002800$

Used to start/stop the operation of the module

ROWHAMMER_ADDRESS1

Address: $0xf0002800 + 0x4 = 0xf0002804$

First attacked address

ROWHAMMER_ADDRESS2

Address: $0xf0002800 + 0x8 = 0xf0002808$

Second attacked address

ROWHAMMER_COUNT

Address: $0xf0002800 + 0xc = 0xf000280c$

This is the number of DMA accesses performed. When the module is enabled, the value can be freely read. When the module is disabled, the register is clear-on-write and has to be read before the next attack.

13.2.7 WRITER

DMA DRAM writer.

Allows to fill DRAM with a predefined pattern using DMA.

Pattern

Provides access to RAM to store access pattern: *mem_addr* and *mem_data*. The pattern address space can be limited using the *data_mask*.

For example, having *mem_addr* filled with $[0x04, 0x02, 0x03, \dots]$ and *mem_data* filled with $[0xff, 0xaa, 0x55, \dots]$ and setting *data_mask* = $0b01$, the pattern [(address, data), ...] written will be: $[(0x04, 0xff), (0x02, 0xaa), (0x04, 0xff), \dots]$ (wraps due to masking).

DRAM memory range that is being accessed can be configured using *mem_mask*.

To use this module, make sure that *ready* is 1, then write the desired number of transfers to *count*. Writing to the *start* CSR will initialize the operation. When the operation is ongoing *ready* will be 0.

Register Listing for WRITER

Register	Address
<i>WRITER_START</i>	<i>0xf0003000</i>
<i>WRITER_READY</i>	<i>0xf0003004</i>
<i>WRITER_MODULO</i>	<i>0xf0003008</i>
<i>WRITER_COUNT</i>	<i>0xf000300c</i>
<i>WRITER_DONE</i>	<i>0xf0003010</i>
<i>WRITER_MEM_MASK</i>	<i>0xf0003014</i>
<i>WRITER_DATA_MASK</i>	<i>0xf0003018</i>
<i>WRITER_DATA_DIV</i>	<i>0xf000301c</i>
<i>WRITER_INVERTER_DIVISOR_MASK</i>	<i>0xf0003020</i>
<i>WRITER_INVERTER_SELECTION_MASK</i>	<i>0xf0003024</i>
<i>WRITER_LAST_ADDRESS</i>	<i>0xf0003028</i>

WRITER_START

Address: 0xf0003000 + 0x0 = 0xf0003000

Write to the register starts the transfer (if ready=1)

WRITER_READY

Address: 0xf0003000 + 0x4 = 0xf0003004

Indicates that the transfer is not ongoing

WRITER_MODULO

Address: 0xf0003000 + 0x8 = 0xf0003008

When set use modulo to calculate DMA transfers address rather than bit masking

WRITER_COUNT

Address: 0xf0003000 + 0xc = 0xf000300c

Desired number of DMA transfers

WRITER_DONE

Address: 0xf0003000 + 0x10 = 0xf0003010

Number of completed DMA transfers

WRITER_MEM_MASK

Address: 0xf0003000 + 0x14 = 0xf0003014

DRAM address mask for DMA transfers

WRITER_DATA_MASK

Address: 0xf0003000 + 0x18 = 0xf0003018

Pattern memory address mask

WRITER_DATA_DIV

Address: $0xf0003000 + 0x1c = 0xf000301c$

Pattern memory address divisor-1

WRITER_INVERTER_DIVISOR_MASK

Address: $0xf0003000 + 0x20 = 0xf0003020$

Divisor mask for selecting rows for which pattern data gets inverted

WRITER_INVERTER_SELECTION_MASK

Address: $0xf0003000 + 0x24 = 0xf0003024$

Selection mask for selecting rows for which pattern data gets inverted

WRITER_LAST_ADDRESS

Address: $0xf0003000 + 0x28 = 0xf0003028$

Number of completed DMA transfers

13.2.8 READER

DMA DRAM reader.

Allows to check DRAM contents against a predefined pattern using DMA.

Pattern

Provides access to RAM to store access pattern: *mem_addr* and *mem_data*. The pattern address space can be limited using the *data_mask*.

For example, having *mem_adr* filled with $[0x04, 0x02, 0x03, \dots]$ and *mem_data* filled with $[0xff, 0xaa, 0x55, \dots]$ and setting *data_mask* = $0b01$, the pattern $[(\text{address}, \text{data}), \dots]$ written will be: $[(0x04, 0xff), (0x02, 0xaa), (0x04, 0xff), \dots]$ (wraps due to masking).

DRAM memory range that is being accessed can be configured using *mem_mask*.

To use this module, make sure that *ready* is 1, then write the desired number of transfers to *count*. Writing to the *start* CSR will initialize the operation. When the operation is ongoing *ready* will be 0.

Reading errors

This module allows to check the locations of errors in the memory. It scans the configured memory area and compares the values read to the predefined pattern. If *skip_fifo* is 0, this module will stop after each error encountered, so that it can be examined. Wait until the *error_ready* CSR is 1. Then use the CSRs *error_offset*, *error_data* and *error_expected* to examine the errors in the current transfer. To continue reading, write 1 to *error_continue* CSR. Setting *skip_fifo* to 1 will disable this behaviour entirely.

The final number of errors can be read from *error_count*. NOTE: This value represents the number of erroneous *DMA transfers*.

The current progress can be read from the *done* CSR.

DFI_SWITCH_REFRESH_COUNT

Address: $0xf0004000 + 0x0 = 0xf0004000$

Count of all refresh commands issued (both by Memory Controller and Payload Executor). Value is latched from internal counter on mode transition: MC -> PE or by writing to the *refresh_update* CSR.

DFI_SWITCH_AT_REFRESH

Address: $0xf0004000 + 0x4 = 0xf0004004$

If set to a value different than 0 the mode transition MC -> PE will be performed only when the value of this register matches the current refresh commands count.

DFI_SWITCH_REFRESH_UPDATE

Address: $0xf0004000 + 0x8 = 0xf0004008$

Force an update of the *refresh_count* CSR.

13.2.10 PAYLOAD_EXECUTOR

Executes the DRAM payload from memory

Instruction decoder

All instructions are 32-bit. The format of most instructions is the same, except for the LOOP instruction, which has a constant TIMESLICE of 1.

NOOP with a TIMESLICE of 0 is a special case which is interpreted as STOP instruction. When this instruction is encountered execution gets finished immediately.

NOTE: TIMESLICE is the number of cycles the instruction will take. This means that instructions other than NOOP that use TIMESLICE=0 are illegal (although will silently be executed as having TIMESLICE=1).

NOTE2: LOOP instruction will *jump* COUNT times, meaning that the “code” inside the loop will effectively be executed COUNT+1 times.

Op codes:

Op	Value
NOOP	0b000
LOOP	0b111
ACT	0b100
PRE	0b101
REF	0b110
ZQC	0b001
READ	0b010

Instruction format:

	LSB		MSB
dfi:	OP_CODE		TIMESLICE ADDRESS
noop:	OP_CODE		TIMESLICE_NOOP
loop:	OP_CODE		COUNT JUMP
stop:	<NOOP>		0

Where ADDRESS depends on the DFI command and is one of:

	LSB		MSB
	RANK		BANK COLUMN
	RANK		BANK ROW

Register Listing for PAYLOAD_EXECUTOR

Register	Address
<i>PAYLOAD_EXECUTOR_START</i>	<i>0xf0004800</i>
<i>PAYLOAD_EXECUTOR_STATUS</i>	<i>0xf0004804</i>
<i>PAYLOAD_EXECUTOR_READ_COUNT</i>	<i>0xf0004808</i>

PAYLOAD_EXECUTOR_START

Address: $0xf0004800 + 0x0 = 0xf0004800$

Writing to this register initializes payload execution

PAYLOAD_EXECUTOR_STATUS

Address: $0xf0004800 + 0x4 = 0xf0004804$

Payload executor status register

Field Name	Description
[0] READY	Indicates that the executor is not running
[1] OVER-FLOW	Indicates the scratchpad memory address counter has overflowed due to the number of READ commands sent during execution

PAYLOAD_EXECUTOR_READ_COUNT

Address: $0xf0004800 + 0x8 = 0xf0004808$

Number of data from READ commands that is stored in the scratchpad memory

13.2.11 CTRL

Register Listing for CTRL

Register	Address
<i>CTRL_RESET</i>	<i>0xf0005000</i>
<i>CTRL_SCRATCH</i>	<i>0xf0005004</i>
<i>CTRL_BUS_ERRORS</i>	<i>0xf0005008</i>

CTRL__RESET

Address: $0xf0005000 + 0x0 = 0xf0005000$

Field	Name	Description
[0]	SOC_RST	Write 1 to this register to reset the full SoC (Pulse Reset)
[1]	CPU_RST	Write 1 to this register to reset the CPU(s) of the SoC (Hold Reset)

CTRL_SCRATCH

Address: $0xf0005000 + 0x4 = 0xf0005004$

Use this register as a scratch space to verify that software read/write accesses to the Wishbone/CSR bus are working correctly. The initial reset value of 0x1234578 can be used to verify endianness.

CTRL_BUS_ERRORS

Address: $0xf0005000 + 0x8 = 0xf0005008$

Total number of Wishbone bus errors (timeouts) since start.

13.2.12 IDENTIFIER_MEM

Register Listing for IDENTIFIER_MEM

Register	Address
<i>IDENTIFIER_MEM</i>	<i>0xf0005800</i>

IDENTIFIER_MEM

Address: $0xf0005800 + 0x0 = 0xf0005800$

8 x 110-bit memory

13.2.16 TIMER0

Timer

Provides a generic Timer core.

The Timer is implemented as a countdown timer that can be used in various modes:

- Polling : Returns current countdown value to software
- One-Shot: Loads itself and stops when value reaches 0
- Periodic: (Re-)Loads itself when value reaches 0

en register allows the user to enable/disable the Timer. When the Timer is enabled, it is automatically loaded with the value of *load* register.

When the Timer reaches 0, it is automatically reloaded with value of *reload* register.

The user can latch the current countdown value by writing to *update_value* register, it will update value register with current countdown value.

To use the Timer in One-Shot mode, the user needs to:

- Disable the timer
- Set the load register to the expected duration
- (Re-)Enable the Timer

To use the Timer in Periodic mode, the user needs to:

- Disable the Timer

- Set the load register to 0
- Set the reload register to the expected period
- Enable the Timer

For both modes, the CPU can be advertised by an IRQ that the duration/period has elapsed. (The CPU can also do software polling with `update_value` and `value` to know the elapsed duration)

Register Listing for TIMERO

Register	Address
<i>TIMERO_LOAD</i>	<i>0xf0007800</i>
<i>TIMERO_RELOAD</i>	<i>0xf0007804</i>
<i>TIMERO_EN</i>	<i>0xf0007808</i>
<i>TIMERO_UPDATE_VALUE</i>	<i>0xf000780c</i>
<i>TIMERO_VALUE</i>	<i>0xf0007810</i>
<i>TIMERO_EV_STATUS</i>	<i>0xf0007814</i>
<i>TIMERO_EV_PENDING</i>	<i>0xf0007818</i>
<i>TIMERO_EV_ENABLE</i>	<i>0xf000781c</i>

TIMERO_LOAD

Address: 0xf0007800 + 0x0 = 0xf0007800

Load value when Timer is (re-)enabled. In One-Shot mode, the value written to this register specifies the Timer's duration in clock cycles.

TIMERO_RELOAD

Address: 0xf0007800 + 0x4 = 0xf0007804

Reload value when Timer reaches 0. In Periodic mode, the value written to this register specify the Timer's period in clock cycles.

TIMERO_EN

Address: 0xf0007800 + 0x8 = 0xf0007808

Enable flag of the Timer. Set this flag to 1 to enable/start the Timer. Set to 0 to disable the Timer.

TIMERO_UPDATE_VALUE

Address: $0xf0007800 + 0xc = 0xf000780c$

Update trigger for the current countdown value. A write to this register latches the current countdown value to value register.

TIMERO_VALUE

Address: $0xf0007800 + 0x10 = 0xf0007810$

Latched countdown value. This value is updated by writing to update_value.

TIMERO_EV_STATUS

Address: $0xf0007800 + 0x14 = 0xf0007814$

This register contains the current raw level of the zero event trigger. Writes to this register have no effect.

Field	Name	Description
[0]	ZERO	Level of the zero event

TIMERO_EV_PENDING

Address: $0xf0007800 + 0x18 = 0xf0007818$

When a zero event occurs, the corresponding bit will be set in this register. To clear the Event, set the corresponding bit in this register.

Field	Name	Description
[0]	ZERO	1 if a <i>zero</i> event occurred. This Event is triggered on a falling edge.

TIMERO_EV_ENABLE

Address: $0xf0007800 + 0x1c = 0xf000781c$

This register enables the corresponding zero events. Write a 0 to this register to disable individual events.

Field	Name	Description
[0]	ZERO	Write a 1 to enable the zero Event

13.2.17 UART

<i>UART_XOVER_EV_ENABLE</i>	<i>0xf0008034</i>
<i>UART_XOVER_TXEMPTY</i>	<i>0xf0008038</i>
<i>UART_XOVER_RXFULL</i>	<i>0xf000803c</i>

UART_RXTX

Address: 0xf0008000 + 0x0 = 0xf0008000

UART_TXFULL

Address: 0xf0008000 + 0x4 = 0xf0008004

TX FIFO Full.

UART_RXEMPTY

Address: 0xf0008000 + 0x8 = 0xf0008008

RX FIFO Empty.

UART_EV_STATUS

Address: $0xf0008000 + 0xc = 0xf000800c$

This register contains the current raw level of the rx event trigger. Writes to this register have no effect.

Field	Name	Description
[0]	TX	Level of the tx event
[1]	RX	Level of the rx event

UART_EV_PENDING

Address: $0xf0008000 + 0x10 = 0xf0008010$

When a rx event occurs, the corresponding bit will be set in this register. To clear the Event, set the corresponding bit in this register.

Field	Name	Description
[0]	TX	1 if a tx event occurred. This Event is triggered on a falling edge.
[1]	RX	1 if a rx event occurred. This Event is triggered on a falling edge.

UART_EV_ENABLE

Address: $0xf0008000 + 0x14 = 0xf0008014$

This register enables the corresponding rx events. Write a 0 to this register to disable individual events.

Field	Name	Description
[0]	TX	Write a 1 to enable the tx Event
[1]	RX	Write a 1 to enable the rx Event

UART_TXEMPTY

Address: $0xf0008000 + 0x18 = 0xf0008018$

TX FIFO Empty.

UART_RXFULL

Address: $0xf0008000 + 0x1c = 0xf000801c$

RX FIFO Full.

UART_XOVER_RXTX

Address: $0xf0008000 + 0x20 = 0xf0008020$

UART_XOVER_TXFULL

Address: $0xf0008000 + 0x24 = 0xf0008024$

TX FIFO Full.

UART_XOVER_RXEMPTY

Address: $0xf0008000 + 0x28 = 0xf0008028$

RX FIFO Empty.

UART_XOVER_EV_STATUS

Address: $0xf0008000 + 0x2c = 0xf000802c$

This register contains the current raw level of the rx event trigger. Writes to this register have no effect.

Field	Name	Description
[0]	TX	Level of the tx event
[1]	RX	Level of the rx event

UART_XOVER_EV_PENDING

Address: $0xf0008000 + 0x30 = 0xf0008030$

When a rx event occurs, the corresponding bit will be set in this register. To clear the Event, set the corresponding bit in this register.

Field	Name	Description
[0]	TX	1 if a tx event occurred. This Event is triggered on a falling edge.
[1]	RX	1 if a rx event occurred. This Event is triggered on a falling edge.

UART_XOVER_EV_ENABLE

Address: $0xf0008000 + 0x34 = 0xf0008034$

This register enables the corresponding rx events. Write a 0 to this register to disable individual events.

Field	Name	Description
[0]	TX	Write a 1 to enable the tx Event
[1]	RX	Write a 1 to enable the rx Event

UART_XOVER_TXEMPTY

Address: $0xf0008000 + 0x38 = 0xf0008038$

TX FIFO Empty.

UART_XOVER_RXFULL

Address: $0xf0008000 + 0x3c = 0xf000803c$

RX FIFO Full.

DOCUMENTATION FOR ROW HAMMER TESTER ZCU104

14.1 Modules

14.1.1 Interrupt Controller

This device has an EventManager-based interrupt system. Individual modules generate *events* which are wired into a central interrupt controller.

When an interrupt occurs, you should look the interrupt number up in the CPU- specific interrupt table and then call the relevant module.

Assigned Interrupts

The following interrupts are assigned on this system:

Interrupt	Module
1	<i>TIMERO</i>
0	<i>UART</i>

14.2 Register Groups

14.2.1 LEDS

Register Listing for LEDS

Register	Address
<i>LEDS_OUT</i>	<i>0xf0000000</i>

LEDS_OUT

Address: $0xf0000000 + 0x0 = 0xf0000000$

Led Output(s) Control.

DDRCTRL_INIT_ERROR

Address: $0xf0001800 + 0x4 = 0xf0001804$

14.2.5 ROWHAMMER

Row Hammer DMA attacker

This module allows to perform a Row Hammer attack by configuring it with two addresses that map to different rows of a single bank. When enabled, it will perform alternating DMA reads from the given locations, which will result in the DRAM controller having to repeatedly open/close rows at each read access.

Register Listing for ROWHAMMER

Register	Address
<i>ROWHAMMER_ENABLED</i>	<i>0xf0002000</i>
<i>ROWHAMMER_ADDRESS1</i>	<i>0xf0002004</i>
<i>ROWHAMMER_ADDRESS2</i>	<i>0xf0002008</i>
<i>ROWHAMMER_COUNT</i>	<i>0xf000200c</i>

ROWHAMMER_ENABLED

Address: 0xf0002000 + 0x0 = 0xf0002000

Used to start/stop the operation of the module

ROWHAMMER_ADDRESS1

Address: 0xf0002000 + 0x4 = 0xf0002004

First attacked address

ROWHAMMER_ADDRESS2

Address: 0xf0002000 + 0x8 = 0xf0002008

Second attacked address

ROWHAMMER_COUNT

Address: 0xf0002000 + 0xc = 0xf000200c

This is the number of DMA accesses performed. When the module is enabled, the value can be freely read. When the module is disabled, the register is clear-on-write and has to be read before the next attack.

14.2.6 WRITER

DMA DRAM writer.

Allows to fill DRAM with a predefined pattern using DMA.

Pattern

Provides access to RAM to store access pattern: *mem_addr* and *mem_data*. The pattern address space can be limited using the *data_mask*.

For example, having *mem_addr* filled with [0x04, 0x02, 0x03, ...] and *mem_data* filled with [0xff, 0xaa, 0x55, ...] and setting *data_mask* = 0b01, the pattern [(address, data), ...] written will be: [(0x04, 0xff), (0x02, 0xaa), (0x04, 0xff), ...] (wraps due to masking).

DRAM memory range that is being accessed can be configured using *mem_mask*.

To use this module, make sure that *ready* is 1, then write the desired number of transfers to *count*. Writing to the *start* CSR will initialize the operation. When the operation is ongoing *ready* will be 0.

Register Listing for WRITER

Register	Address
<i>WRITER_START</i>	0xf0002800
<i>WRITER_READY</i>	0xf0002804
<i>WRITER_MODULO</i>	0xf0002808
<i>WRITER_COUNT</i>	0xf000280c
<i>WRITER_DONE</i>	0xf0002810
<i>WRITER_MEM_MASK</i>	0xf0002814
<i>WRITER_DATA_MASK</i>	0xf0002818
<i>WRITER_DATA_DIV</i>	0xf000281c
<i>WRITER_INVERTER_DIVISOR_MASK</i>	0xf0002820
<i>WRITER_INVERTER_SELECTION_MASK</i>	0xf0002824
<i>WRITER_LAST_ADDRESS</i>	0xf0002828

WRITER_START

Address: $0xf0002800 + 0x0 = 0xf0002800$

Write to the register starts the transfer (if ready=1)

WRITER_READY

Address: $0xf0002800 + 0x4 = 0xf0002804$

Indicates that the transfer is not ongoing

WRITER_MODULO

Address: $0xf0002800 + 0x8 = 0xf0002808$

When set use modulo to calculate DMA transfers address rather than bit masking

WRITER_COUNT

Address: $0xf0002800 + 0xc = 0xf000280c$

Desired number of DMA transfers

WRITER_DONE

Address: $0xf0002800 + 0x10 = 0xf0002810$

Number of completed DMA transfers

WRITER_MEM_MASK

Address: $0xf0002800 + 0x14 = 0xf0002814$

DRAM address mask for DMA transfers

WRITER_DATA_MASK

Address: $0xf0002800 + 0x18 = 0xf0002818$

Pattern memory address mask

WRITER_DATA_DIV

Address: $0xf0002800 + 0x1c = 0xf000281c$

Pattern memory address divisor-1

WRITER_INVERTER_DIVISOR_MASK

Address: $0xf0002800 + 0x20 = 0xf0002820$

Divisor mask for selecting rows for which pattern data gets inverted

WRITER_INVERTER_SELECTION_MASK

Address: $0xf0002800 + 0x24 = 0xf0002824$

Selection mask for selecting rows for which pattern data gets inverted

WRITER_LAST_ADDRESS

Address: $0xf0002800 + 0x28 = 0xf0002828$

Number of completed DMA transfers

14.2.7 READER

DMA DRAM reader.

Allows to check DRAM contents against a predefined pattern using DMA.

Pattern

Provides access to RAM to store access pattern: *mem_addr* and *mem_data*. The pattern address space can be limited using the *data_mask*.

For example, having *mem_addr* filled with $[0x04, 0x02, 0x03, \dots]$ and *mem_data* filled with $[0xff, 0xaa, 0x55, \dots]$ and setting *data_mask* = $0b01$, the pattern $[(\text{address}, \text{data}), \dots]$ written will be: $[(0x04, 0xff), (0x02, 0xaa), (0x04, 0xff), \dots]$ (wraps due to masking).

DRAM memory range that is being accessed can be configured using *mem_mask*.

To use this module, make sure that *ready* is 1, then write the desired number of transfers to *count*. Writing to the *start* CSR will initialize the operation. When the operation is ongoing *ready* will be 0.

Reading errors

This module allows to check the locations of errors in the memory. It scans the configured memory area and compares the values read to the predefined pattern. If *skip_fifo* is 0, this module will stop after each error encountered, so that it can be examined. Wait until the *error_ready* CSR is 1. Then use the CSRs *error_offset*, *error_data* and *error_expected* to examine the errors in the current transfer. To continue reading, write 1 to *error_continue* CSR. Setting *skip_fifo* to 1 will disable this behaviour entirely.

The final number of errors can be read from *error_count*. NOTE: This value represents the number of erroneous *DMA transfers*.

The current progress can be read from the *done* CSR.

Address: $0xf0003000 + 0x80 = 0xf0003080$

Bits 384-415 of *READER_ERROR_EXPECTED*.

READER_ERROR_EXPECTED11

Address: $0xf0003000 + 0x84 = 0xf0003084$

Bits 352-383 of *READER_ERROR_EXPECTED*.

READER_ERROR_EXPECTED10

Address: $0xf0003000 + 0x88 = 0xf0003088$

Bits 320-351 of *READER_ERROR_EXPECTED*.

READER_ERROR_EXPECTED9

Address: $0xf0003000 + 0x8c = 0xf000308c$

Bits 288-319 of *READER_ERROR_EXPECTED*.

READER_ERROR_EXPECTED8

Address: $0xf0003000 + 0x90 = 0xf0003090$

Bits 256-287 of *READER_ERROR_EXPECTED*.

READER_ERROR_EXPECTED7

Address: $0xf0003000 + 0x94 = 0xf0003094$

Bits 224-255 of *READER_ERROR_EXPECTED*.

READER_ERROR_EXPECTED6

Address: $0xf0003000 + 0x98 = 0xf0003098$

Bits 192-223 of *READER_ERROR_EXPECTED*.

READER_ERROR_EXPECTED5

Address: $0xf0003000 + 0x9c = 0xf000309c$

Bits 160-191 of *READER_ERROR_EXPECTED*.

READER_ERROR_EXPECTED4

Address: $0xf0003000 + 0xa0 = 0xf00030a0$

Bits 128-159 of *READER_ERROR_EXPECTED*.

READER_ERROR_EXPECTED3

Address: $0xf0003000 + 0xa4 = 0xf00030a4$

Bits 96-127 of *READER_ERROR_EXPECTED*.

READER_ERROR_EXPECTED2

Address: $0xf0003000 + 0xa8 = 0xf00030a8$

Bits 64-95 of *READER_ERROR_EXPECTED*.

READER_ERROR_EXPECTED1

Address: $0xf0003000 + 0xac = 0xf00030ac$

Bits 32-63 of *READER_ERROR_EXPECTED*.

READER_ERROR_EXPECTED0

Address: $0xf0003000 + 0xb0 = 0xf00030b0$

Bits 0-31 of *READER_ERROR_EXPECTED*.

READER_ERROR_READY

Address: $0xf0003000 + 0xb4 = 0xf00030b4$

Error detected and ready to read

READER_ERROR_CONTINUE

Address: $0xf0003000 + 0xb8 = 0xf00030b8$

Continue reading until the next error

14.2.8 DFI_SWITCH

Register Listing for DFI_SWITCH

Register	Address
<i>DFI_SWITCH_REFRESH_COUNT</i>	<i>0xf0003800</i>
<i>DFI_SWITCH_AT_REFRESH</i>	<i>0xf0003804</i>
<i>DFI_SWITCH_REFRESH_UPDATE</i>	<i>0xf0003808</i>

DFI_SWITCH_REFRESH_COUNT

Address: $0xf0003800 + 0x0 = 0xf0003800$

Count of all refresh commands issued (both by Memory Controller and Payload Executor). Value is latched from internal counter on mode transition: MC -> PE or by writing to the *refresh_update* CSR.

DFI_SWITCH_AT_REFRESH

Address: $0xf0003800 + 0x4 = 0xf0003804$

If set to a value different than 0 the mode transition MC -> PE will be performed only when the value of this register matches the current refresh commands count.

DFI_SWITCH_REFRESH_UPDATE

Address: $0xf0003800 + 0x8 = 0xf0003808$

Force an update of the *refresh_count* CSR.

14.2.9 PAYLOAD_EXECUTOR

Executes the DRAM payload from memory

Instruction decoder

All instructions are 32-bit. The format of most instructions is the same, except for the LOOP instruction, which has a constant TIMESLICE of 1.

NOOP with a TIMESLICE of 0 is a special case which is interpreted as STOP instruction. When this instruction is encountered execution gets finished immediately.

NOTE: TIMESLICE is the number of cycles the instruction will take. This means that instructions other than NOOP that use TIMESLICE=0 are illegal (although will silently be executed as having TIMESLICE=1).

NOTE2: LOOP instruction will *jump* COUNT times, meaning that the “code” inside the loop will effectively be executed COUNT+1 times.

Op codes:

Op	Value
NOOP	0b000
LOOP	0b111
ACT	0b100
PRE	0b101
REF	0b110
ZQC	0b001
READ	0b010

Instruction format:

	LSB		MSB
dfi:	OP_CODE	TIMESLICE	ADDRESS
noop:	OP_CODE	TIMESLICE_NOOP	
loop:	OP_CODE	COUNT	JUMP
stop:	<NOOP>	0	

Where ADDRESS depends on the DFI command and is one of:

	LSB		MSB
	RANK	BANK	COLUMN
	RANK	BANK	ROW

Register Listing for PAYLOAD_EXECUTOR

Register	Address
<i>PAYLOAD_EXECUTOR_START</i>	<i>0xf0004000</i>
<i>PAYLOAD_EXECUTOR_STATUS</i>	<i>0xf0004004</i>
<i>PAYLOAD_EXECUTOR_READ_COUNT</i>	<i>0xf0004008</i>

PAYLOAD_EXECUTOR_START

Address: $0xf0004000 + 0x0 = 0xf0004000$

Writing to this register initializes payload execution

PAYLOAD_EXECUTOR_STATUS

Address: $0xf0004000 + 0x4 = 0xf0004004$

Payload executor status register

Field	Name	Description
[0]	READY	Indicates that the executor is not running
[1]	OVER-FLOW	Indicates the scratchpad memory address counter has overflowed due to the number of READ commands sent during execution

PAYLOAD_EXECUTOR_READ_COUNT

Address: $0xf0004000 + 0x8 = 0xf0004008$

Number of data from READ commands that is stored in the scratchpad memory

14.2.10 I2C

Register Listing for I2C

Register	Address
<i>I2C_W</i>	<i>0xf0004800</i>
<i>I2C_R</i>	<i>0xf0004804</i>

I2C_W

Address: $0xf0004800 + 0x0 = 0xf0004800$

Field	Name	Description

I2C_R

Address: $0xf0004800 + 0x4 = 0xf0004804$

Field	Name	Description

14.2.11 CTRL

Register Listing for CTRL

Register	Address
<i>CTRL_RESET</i>	<i>0xf0005000</i>
<i>CTRL_SCRATCH</i>	<i>0xf0005004</i>
<i>CTRL_BUS_ERRORS</i>	<i>0xf0005008</i>

CTRL_RESET

Address: $0xf0005000 + 0x0 = 0xf0005000$

Field	Name	Description
[0]	SOC_RST	Write 1 to this register to reset the full SoC (Pulse Reset)
[1]	CPU_RST	Write 1 to this register to reset the CPU(s) of the SoC (Hold Reset)

CTRL_SCRATCH

Address: $0xf0005000 + 0x4 = 0xf0005004$

Use this register as a scratch space to verify that software read/write accesses to the Wishbone/CSR bus are working correctly. The initial reset value of 0x1234578 can be used to verify endianness.

CTRL_BUS_ERRORS

Address: $0xf0005000 + 0x8 = 0xf0005008$

Total number of Wishbone bus errors (timeouts) since start.

14.2.12 IDENTIFIER_MEM

Register Listing for IDENTIFIER_MEM

Register	Address
<i>IDENTIFIER_MEM</i>	<i>0xf0005800</i>

IDENTIFIER_MEM

Address: $0xf0005800 + 0x0 = 0xf0005800$

8 x 113-bit memory

14.2.13 SDRAM

Register Listing for SDRAM

SDRAM_DFII_CONTROL

Address: $0xf0006000 + 0x0 = 0xf0006000$

Control DFI signals common to all phases

Field	Name	Description						
[0]	SEL	<table border="1"> <thead> <tr> <th>Value</th> <th>Description</th> </tr> </thead> <tbody> <tr> <td>0b0</td> <td>Software (CPU) control.</td> </tr> <tr> <td>0b1</td> <td>Hardware control (default).</td> </tr> </tbody> </table>	Value	Description	0b0	Software (CPU) control.	0b1	Hardware control (default).
Value	Description							
0b0	Software (CPU) control.							
0b1	Hardware control (default).							
[1]	CKE	DFI clock enable bus						
[2]	ODT	DFI on-die termination bus						
[3]	RESET_N	DFI clock reset bus						

SDRAM_DFII_PIO_COMMAND

Address: $0xf0006000 + 0x4 = 0xf0006004$

Control DFI signals on a single phase

Field	Name	Description
[0]	CS	DFI chip select bus
[1]	WE	DFI write enable bus
[2]	CAS	DFI column address strobe bus
[3]	RAS	DFI row address strobe bus
[4]	WREN	DFI write data enable bus
[5]	RDEN	DFI read data enable bus

SDRAM_DFII_PIO_COMMAND_ISSUE

Address: $0xf0006000 + 0x8 = 0xf0006008$

SDRAM_DFII_PIO_ADDRESS

Address: $0xf0006000 + 0xc = 0xf000600c$

DFI address bus

SDRAM_DFII_PIO_BADDRESS

Address: $0xf0006000 + 0x10 = 0xf0006010$

DFI bank address bus

SDRAM_DFII_PIO_WRDATA3

Address: $0xf0006000 + 0x14 = 0xf0006014$

Bits 96-127 of *SDRAM_DFII_PIO_WRDATA*. DFI write data bus

SDRAM_DFII_PIO_WRDATA2

Address: $0xf0006000 + 0x18 = 0xf0006018$

Bits 64-95 of *SDRAM_DFII_PIO_WRDATA*.

SDRAM_DFII_PIO_WRDATA1

Address: $0xf0006000 + 0x1c = 0xf000601c$

Bits 32-63 of *SDRAM_DFII_PIO_WRDATA*.

SDRAM_DFII_PIO_WRDATA0

Address: $0xf0006000 + 0x20 = 0xf0006020$

14.2.16 TIMERO

Timer

Provides a generic Timer core.

The Timer is implemented as a countdown timer that can be used in various modes:

- Polling : Returns current countdown value to software
- One-Shot: Loads itself and stops when value reaches 0
- Periodic: (Re-)Loads itself when value reaches 0

en register allows the user to enable/disable the Timer. When the Timer is enabled, it is automatically loaded with the value of *load* register.

When the Timer reaches 0, it is automatically reloaded with value of *reload* register.

The user can latch the current countdown value by writing to *update_value* register, it will update *value* register with current countdown value.

To use the Timer in One-Shot mode, the user needs to:

- Disable the timer
- Set the load register to the expected duration
- (Re-)Enable the Timer

To use the Timer in Periodic mode, the user needs to:

- Disable the Timer
- Set the load register to 0
- Set the reload register to the expected period
- Enable the Timer

For both modes, the CPU can be advertised by an IRQ that the duration/period has elapsed. (The CPU can also do software polling with *update_value* and *value* to know the elapsed duration)

Register Listing for TIMERO

Register	Address
<i>TIMERO_LOAD</i>	<i>0xf0007800</i>
<i>TIMERO_RELOAD</i>	<i>0xf0007804</i>
<i>TIMERO_EN</i>	<i>0xf0007808</i>
<i>TIMERO_UPDATE_VALUE</i>	<i>0xf000780c</i>
<i>TIMERO_VALUE</i>	<i>0xf0007810</i>
<i>TIMERO_EV_STATUS</i>	<i>0xf0007814</i>
<i>TIMERO_EV_PENDING</i>	<i>0xf0007818</i>
<i>TIMERO_EV_ENABLE</i>	<i>0xf000781c</i>

TIMERO_LOAD

Address: $0xf0007800 + 0x0 = 0xf0007800$

Load value when Timer is (re-)enabled. In One-Shot mode, the value written to this register specifies the Timer's duration in clock cycles.

TIMERO_RELOAD

Address: $0xf0007800 + 0x4 = 0xf0007804$

Reload value when Timer reaches 0. In Periodic mode, the value written to this register specify the Timer's period in clock cycles.

TIMERO_EN

Address: $0xf0007800 + 0x8 = 0xf0007808$

Enable flag of the Timer. Set this flag to 1 to enable/start the Timer. Set to 0 to disable the Timer.

TIMERO_UPDATE_VALUE

Address: $0xf0007800 + 0xc = 0xf000780c$

Update trigger for the current countdown value. A write to this register latches the current countdown value to value register.

TIMERO_VALUE

Address: $0xf0007800 + 0x10 = 0xf0007810$

Latched countdown value. This value is updated by writing to update_value.

TIMERO_EV_STATUS

Address: $0xf0007800 + 0x14 = 0xf0007814$

This register contains the current raw level of the zero event trigger. Writes to this register have no effect.

Field	Name	Description
[0]	ZERO	Level of the zero event

TIMERO_EV_PENDING

Address: $0xf0007800 + 0x18 = 0xf0007818$

When a zero event occurs, the corresponding bit will be set in this register. To clear the Event, set the corresponding bit in this register.

Field	Name	Description
[0]	ZERO	1 if a <i>zero</i> event occurred. This Event is triggered on a falling edge.

TIMERO_EV_ENABLE

Address: $0xf0007800 + 0x1c = 0xf000781c$

This register enables the corresponding zero events. Write a 0 to this register to disable individual events.

Field	Name	Description
[0]	ZERO	Write a 1 to enable the zero Event

14.2.17 UART

UART_RXTX

Address: $0xf0008000 + 0x0 = 0xf0008000$

UART_TXFULL

Address: $0xf0008000 + 0x4 = 0xf0008004$

TX FIFO Full.

UART_RXEMPTY

Address: $0xf0008000 + 0x8 = 0xf0008008$

RX FIFO Empty.

UART_EV_STATUS

Address: $0xf0008000 + 0xc = 0xf000800c$

This register contains the current raw level of the rx event trigger. Writes to this register have no effect.

Field	Name	Description
[0]	TX	Level of the tx event
[1]	RX	Level of the rx event

UART_EV_PENDING

Address: $0xf0008000 + 0x10 = 0xf0008010$

When a rx event occurs, the corresponding bit will be set in this register. To clear the Event, set the corresponding bit in this register.

Field	Name	Description
[0]	TX	1 if a tx event occurred. This Event is triggered on a falling edge.
[1]	RX	1 if a rx event occurred. This Event is triggered on a falling edge.

UART_EV_ENABLE

Address: $0xf0008000 + 0x14 = 0xf0008014$

This register enables the corresponding rx events. Write a 0 to this register to disable individual events.

Field	Name	Description
[0]	TX	Write a 1 to enable the tx Event
[1]	RX	Write a 1 to enable the rx Event

UART_TXEMPTY

Address: $0xf0008000 + 0x18 = 0xf0008018$

TX FIFO Empty.

UART_RXFULL

Address: $0xf0008000 + 0x1c = 0xf000801c$

RX FIFO Full.

UART_XOVER_RXTX

Address: $0xf0008000 + 0x20 = 0xf0008020$

UART_XOVER_TXFULL

Address: $0xf0008000 + 0x24 = 0xf0008024$

TX FIFO Full.

UART_XOVER_RXEMPTY

Address: $0xf0008000 + 0x28 = 0xf0008028$

RX FIFO Empty.

UART_XOVER_EV_STATUS

Address: $0xf0008000 + 0x2c = 0xf000802c$

This register contains the current raw level of the rx event trigger. Writes to this register have no effect.

Field	Name	Description
[0]	TX	Level of the tx event
[1]	RX	Level of the rx event

UART_XOVER_EV_PENDING

Address: $0xf0008000 + 0x30 = 0xf0008030$

When a rx event occurs, the corresponding bit will be set in this register. To clear the Event, set the corresponding bit in this register.

Field	Name	Description
[0]	TX	1 if a tx event occurred. This Event is triggered on a falling edge.
[1]	RX	1 if a rx event occurred. This Event is triggered on a falling edge.

UART_XOVER_EV_ENABLE

Address: $0xf0008000 + 0x34 = 0xf0008034$

This register enables the corresponding rx events. Write a 0 to this register to disable individual events.

Field	Name	Description
[0]	TX	Write a 1 to enable the tx Event
[1]	RX	Write a 1 to enable the rx Event

UART_XOVER_TXEMPTY

Address: $0xf0008000 + 0x38 = 0xf0008038$

TX FIFO Empty.

UART_XOVER_RXFULL

Address: 0xf0008000 + 0x3c = 0xf000803c

RX FIFO Full.

DOCUMENTATION FOR ROW HAMMER TESTER DATA CENTER
DRAM TESTER

15.1 Modules

15.1.1 Interrupt Controller

This device has an EventManager-based interrupt system. Individual modules generate *events* which are wired into a central interrupt controller.

When an interrupt occurs, you should look the interrupt number up in the CPU- specific interrupt table and then call the relevant module.

Assigned Interrupts

The following interrupts are assigned on this system:

Interrupt	Module
1	<i>TIMERO</i>
0	<i>UART</i>

15.2 Register Groups

15.2.1 LEDS

DDRCTRL_INIT_ERROR

Address: $0xf0001800 + 0x4 = 0xf0001804$

15.2.5 ROWHAMMER

Row Hammer DMA attacker

This module allows to perform a Row Hammer attack by configuring it with two addresses that map to different rows of a single bank. When enabled, it will perform alternating DMA reads from the given locations, which will result in the DRAM controller having to repeatedly open/close rows at each read access.

Register Listing for ROWHAMMER

Register	Address
<i>ROWHAMMER_ENABLED</i>	<i>0xf0002000</i>
<i>ROWHAMMER_ADDRESS1</i>	<i>0xf0002004</i>
<i>ROWHAMMER_ADDRESS2</i>	<i>0xf0002008</i>
<i>ROWHAMMER_COUNT</i>	<i>0xf000200c</i>

ROWHAMMER_ENABLED

Address: 0xf0002000 + 0x0 = 0xf0002000

Used to start/stop the operation of the module

ROWHAMMER_ADDRESS1

Address: 0xf0002000 + 0x4 = 0xf0002004

First attacked address

ROWHAMMER_ADDRESS2

Address: 0xf0002000 + 0x8 = 0xf0002008

Second attacked address

ROWHAMMER_COUNT

Address: 0xf0002000 + 0xc = 0xf000200c

This is the number of DMA accesses performed. When the module is enabled, the value can be freely read. When the module is disabled, the register is clear-on-write and has to be read before the next attack.

15.2.6 WRITER

DMA DRAM writer.

Allows to fill DRAM with a predefined pattern using DMA.

Pattern

Provides access to RAM to store access pattern: *mem_addr* and *mem_data*. The pattern address space can be limited using the *data_mask*.

For example, having *mem_addr* filled with [*0x04, 0x02, 0x03, ...*] and *mem_data* filled with [*0xff, 0xaa, 0x55, ...*] and setting *data_mask* = *0b01*, the pattern [(address, data), ...] written will be: [(*0x04, 0xff*), (*0x02, 0xaa*), (*0x04, 0xff*), ...] (wraps due to masking).

DRAM memory range that is being accessed can be configured using *mem_mask*.

To use this module, make sure that *ready* is 1, then write the desired number of transfers to *count*. Writing to the *start* CSR will initialize the operation. When the operation is ongoing *ready* will be 0.

Register Listing for WRITER

<i>WRITER_INVERTER_DIVISOR_MASK</i>	<i>0xf0002820</i>
<i>WRITER_INVERTER_SELECTION_MASK</i>	<i>0xf0002824</i>
<i>WRITER_LAST_ADDRESS</i>	<i>0xf0002828</i>

WRITER_START

Address: *0xf0002800* + *0x0* = *0xf0002800*

Write to the register starts the transfer (if ready=1)

WRITER_READY

Address: *0xf0002800* + *0x4* = *0xf0002804*

Indicates that the transfer is not ongoing

WRITER_MODULO

Address: $0xf0002800 + 0x8 = 0xf0002808$

When set use modulo to calculate DMA transfers address rather than bit masking

WRITER_COUNT

Address: $0xf0002800 + 0xc = 0xf000280c$

Desired number of DMA transfers

WRITER_DONE

Address: $0xf0002800 + 0x10 = 0xf0002810$

Number of completed DMA transfers

WRITER_MEM_MASK

Address: $0xf0002800 + 0x14 = 0xf0002814$

DRAM address mask for DMA transfers

WRITER_DATA_MASK

Address: $0xf0002800 + 0x18 = 0xf0002818$

Pattern memory address mask

WRITER_DATA_DIV

Address: $0xf0002800 + 0x1c = 0xf000281c$

Pattern memory address divisor-1

WRITER_INVERTER_DIVISOR_MASK

Address: $0xf0002800 + 0x20 = 0xf0002820$

Divisor mask for selecting rows for which pattern data gets inverted

WRITER_INVERTER_SELECTION_MASK

Address: $0xf0002800 + 0x24 = 0xf0002824$

Selection mask for selecting rows for which pattern data gets inverted

WRITER_LAST_ADDRESS

Address: $0xf0002800 + 0x28 = 0xf0002828$

Number of completed DMA transfers

15.2.7 READER

DMA DRAM reader.

Allows to check DRAM contents against a predefined pattern using DMA.

Pattern

Provides access to RAM to store access pattern: *mem_addr* and *mem_data*. The pattern address space can be limited using the *data_mask*.

For example, having *mem_addr* filled with $[0x04, 0x02, 0x03, \dots]$ and *mem_data* filled with $[0xff, 0xaa, 0x55, \dots]$ and setting *data_mask* = $0b01$, the pattern $[(\text{address}, \text{data}), \dots]$ written will be: $[(0x04, 0xff), (0x02, 0xaa), (0x04, 0xff), \dots]$ (wraps due to masking).

DRAM memory range that is being accessed can be configured using *mem_mask*.

To use this module, make sure that *ready* is 1, then write the desired number of transfers to *count*. Writing to the *start* CSR will initialize the operation. When the operation is ongoing *ready* will be 0.

Reading errors

This module allows to check the locations of errors in the memory. It scans the configured memory area and compares the values read to the predefined pattern. If *skip_fifo* is 0, this module will stop after each error encountered, so that it can be examined. Wait until the *error_ready* CSR is 1. Then use the CSRs *error_offset*, *error_data* and *error_expected* to examine the errors in the current transfer. To continue reading, write 1 to *error_continue* CSR. Setting *skip_fifo* to 1 will disable this behaviour entirely.

The final number of errors can be read from *error_count*. NOTE: This value represents the number of erroneous *DMA transfers*.

The current progress can be read from the *done* CSR.

Pattern memory address mask

READER_DATA_DIV

Address: 0xf0003000 + 0x1c = 0xf000301c

Pattern memory address divisor-1

READER_INVERTER_DIVISOR_MASK

Address: $0xf0003000 + 0x20 = 0xf0003020$

Divisor mask for selecting rows for which pattern data gets inverted

READER_INVERTER_SELECTION_MASK

Address: $0xf0003000 + 0x24 = 0xf0003024$

Selection mask for selecting rows for which pattern data gets inverted

READER_ERROR_COUNT

Address: $0xf0003000 + 0x28 = 0xf0003028$

Number of errors detected

READER_SKIP_FIFO

Address: $0xf0003000 + 0x2c = 0xf000302c$

Skip waiting for user to read the errors FIFO

READER_ERROR_OFFSET

Address: $0xf0003000 + 0x30 = 0xf0003030$

Current offset of the error

READER_ERROR_DATA7

Address: $0xf0003000 + 0x34 = 0xf0003034$

Bits 224-255 of *READER_ERROR_DATA*. Erroneous value read from DRAM memory

READER_ERROR_DATA6

Address: $0xf0003000 + 0x38 = 0xf0003038$

Bits 192-223 of *READER_ERROR_DATA*.

READER_ERROR_DATA5

Address: $0xf0003000 + 0x3c = 0xf000303c$

Bits 160-191 of *READER_ERROR_DATA*.

READER_ERROR_DATA4

Address: $0xf0003000 + 0x40 = 0xf0003040$

Bits 128-159 of *READER_ERROR_DATA*.

READER_ERROR_DATA3

Address: $0xf0003000 + 0x44 = 0xf0003044$

Bits 96-127 of *READER_ERROR_DATA*.

READER_ERROR_DATA2

Address: $0xf0003000 + 0x48 = 0xf0003048$

Bits 64-95 of *READER_ERROR_DATA*.

READER_ERROR_DATA1

Address: $0xf0003000 + 0x4c = 0xf000304c$

Bits 32-63 of *READER_ERROR_DATA*.

READER_ERROR_DATA0

Address: $0xf0003000 + 0x50 = 0xf0003050$

Bits 0-31 of *READER_ERROR_DATA*.

READER_ERROR_EXPECTED7

Address: $0xf0003000 + 0x54 = 0xf0003054$

Bits 224-255 of *READER_ERROR_EXPECTED*. Value expected to be read from DRAM memory

READER_ERROR_EXPECTED6

Address: $0xf0003000 + 0x58 = 0xf0003058$

Bits 192-223 of *READER_ERROR_EXPECTED*.

READER_ERROR_EXPECTED5

Address: $0xf0003000 + 0x5c = 0xf000305c$

Bits 160-191 of *READER_ERROR_EXPECTED*.

READER_ERROR_EXPECTED4

Address: $0xf0003000 + 0x60 = 0xf0003060$

Bits 128-159 of *READER_ERROR_EXPECTED*.

READER_ERROR_EXPECTED3

Address: $0xf0003000 + 0x64 = 0xf0003064$

Bits 96-127 of *READER_ERROR_EXPECTED*.

READER_ERROR_EXPECTED2

Address: $0xf0003000 + 0x68 = 0xf0003068$

Bits 64-95 of *READER_ERROR_EXPECTED*.

READER_ERROR_EXPECTED1

Address: $0xf0003000 + 0x6c = 0xf000306c$

Bits 32-63 of *READER_ERROR_EXPECTED*.

READER_ERROR_EXPECTED0

Address: $0xf0003000 + 0x70 = 0xf0003070$

Bits 0-31 of *READER_ERROR_EXPECTED*.

READER_ERROR_READY

Address: $0xf0003000 + 0x74 = 0xf0003074$

Error detected and ready to read

READER_ERROR_CONTINUE

Address: $0xf0003000 + 0x78 = 0xf0003078$

Continue reading until the next error

15.2.8 DFI_SWITCH

Register Listing for DFI_SWITCH

Register	Address
<i>DFI_SWITCH_REFRESH_COUNT</i>	<i>0xf0003800</i>
<i>DFI_SWITCH_AT_REFRESH</i>	<i>0xf0003804</i>
<i>DFI_SWITCH_REFRESH_UPDATE</i>	<i>0xf0003808</i>

DFI_SWITCH_REFRESH_COUNT

Address: $0xf0003800 + 0x0 = 0xf0003800$

Count of all refresh commands issued (both by Memory Controller and Payload Executor). Value is latched from internal counter on mode transition: MC -> PE or by writing to the *refresh_update* CSR.

DFI_SWITCH_AT_REFRESH

Address: $0xf0003800 + 0x4 = 0xf0003804$

If set to a value different than 0 the mode transition MC -> PE will be performed only when the value of this register matches the current refresh commands count.

DFI_SWITCH_REFRESH_UPDATE

Address: $0xf0003800 + 0x8 = 0xf0003808$

Force an update of the *refresh_count* CSR.

15.2.9 PAYLOAD_EXECUTOR

Executes the DRAM payload from memory

Instruction decoder

All instructions are 32-bit. The format of most instructions is the same, except for the LOOP instruction, which has a constant TIMESLICE of 1.

NOOP with a TIMESLICE of 0 is a special case which is interpreted as STOP instruction. When this instruction is encountered execution gets finished immediately.

NOTE: TIMESLICE is the number of cycles the instruction will take. This means that instructions other than NOOP that use TIMESLICE=0 are illegal (although will silently be executed as having TIMESLICE=1).

NOTE2: LOOP instruction will *jump* COUNT times, meaning that the “code” inside the loop will effectively be executed COUNT+1 times.

Op codes:

Op	Value
NOOP	0b000
LOOP	0b111
ACT	0b100
PRE	0b101
REF	0b110
ZQC	0b001
READ	0b010

Instruction format:

	LSB		MSB
dfi:	OP_CODE		TIMESLICE ADDRESS
noop:	OP_CODE		TIMESLICE_NOOP
loop:	OP_CODE		COUNT JUMP
stop:	<NOOP>		0

Where ADDRESS depends on the DFI command and is one of:

	LSB		MSB
	RANK		BANK COLUMN
	RANK		BANK ROW

Register Listing for PAYLOAD_EXECUTOR

Register	Address
<i>PAYLOAD_EXECUTOR_START</i>	<i>0xf0004000</i>
<i>PAYLOAD_EXECUTOR_STATUS</i>	<i>0xf0004004</i>
<i>PAYLOAD_EXECUTOR_READ_COUNT</i>	<i>0xf0004008</i>

PAYLOAD_EXECUTOR_START

Address: $0xf0004000 + 0x0 = 0xf0004000$

Writing to this register initializes payload execution

PAYLOAD_EXECUTOR_STATUS

Address: $0xf0004000 + 0x4 = 0xf0004004$

Payload executor status register

Field Name	Description
[0] READY	Indicates that the executor is not running
[1] OVER-FLOW	Indicates the scratchpad memory address counter has overflowed due to the number of READ commands sent during execution

PAYLOAD_EXECUTOR_READ_COUNT

Address: $0xf0004000 + 0x8 = 0xf0004008$

Number of data from READ commands that is stored in the scratchpad memory

15.2.10 I2C

Register Listing for I2C

Register	Address
<i>I2C_W</i>	<i>0xf0004800</i>
<i>I2C_R</i>	<i>0xf0004804</i>

I2C_W

Address: $0xf0004800 + 0x0 = 0xf0004800$

Field	Name	Description

I2C_R

Address: $0xf0004800 + 0x4 = 0xf0004804$

15.2.11 CTRL

Register Listing for CTRL

Register	Address
<i>CTRL_RESET</i>	<i>0xf0005000</i>
<i>CTRL_SCRATCH</i>	<i>0xf0005004</i>
<i>CTRL_BUS_ERRORS</i>	<i>0xf0005008</i>

CTRL_RESET

Address: $0xf0005000 + 0x0 = 0xf0005000$

Field	Name	Description
[0]	SOC_RST	Write 1 to this register to reset the full SoC (Pulse Reset)
[1]	CPU_RST	Write 1 to this register to reset the CPU(s) of the SoC (Hold Reset)

CTRL_SCRATCH

Address: $0xf0005000 + 0x4 = 0xf0005004$

Use this register as a scratch space to verify that software read/write accesses to the Wishbone/CSR bus are working correctly. The initial reset value of 0x1234578 can be used to verify endianness.

CTRL_BUS_ERRORS

Address: $0xf0005000 + 0x8 = 0xf0005008$

Total number of Wishbone bus errors (timeouts) since start.

SDRAM_DFII_CONTROL

Address: $0xf0006800 + 0x0 = 0xf0006800$

Control DFI signals common to all phases

Field	Name	Description						
[0]	SEL	<table border="1"> <thead> <tr> <th>Value</th> <th>Description</th> </tr> </thead> <tbody> <tr> <td>0b0</td> <td>Software (CPU) control.</td> </tr> <tr> <td>0b1</td> <td>Hardware control (default).</td> </tr> </tbody> </table>	Value	Description	0b0	Software (CPU) control.	0b1	Hardware control (default).
Value	Description							
0b0	Software (CPU) control.							
0b1	Hardware control (default).							
[1]	CKE	DFI clock enable bus						
[2]	ODT	DFI on-die termination bus						
[3]	RESET_N	DFI clock reset bus						

SDRAM_DFII_PIO_COMMAND

Address: $0xf0006800 + 0x4 = 0xf0006804$

Control DFI signals on a single phase

Field	Name	Description
[0]	CS	DFI chip select bus
[1]	WE	DFI write enable bus
[2]	CAS	DFI column address strobe bus
[3]	RAS	DFI row address strobe bus
[4]	WREN	DFI write data enable bus
[5]	RDEN	DFI read data enable bus

SDRAM_DFII_PIO_COMMAND_ISSUE

Address: $0xf0006800 + 0x8 = 0xf0006808$

SDRAM_DFII_PIO_ADDRESS

Address: $0xf0006800 + 0xc = 0xf000680c$

DFI address bus

SDRAM_DFII_PIO_BADDRESS

Address: $0xf0006800 + 0x10 = 0xf0006810$

DFI bank address bus

SDRAM_DFII_PIO_WRDATA1

Address: $0xf0006800 + 0x14 = 0xf0006814$

Bits 32-63 of *SDRAM_DFII_PIO_WRDATA*. DFI write data bus

15.2.17 TIMER0

Timer

Provides a generic Timer core.

The Timer is implemented as a countdown timer that can be used in various modes:

- Polling : Returns current countdown value to software
- One-Shot: Loads itself and stops when value reaches 0
- Periodic: (Re-)Loads itself when value reaches 0

en register allows the user to enable/disable the Timer. When the Timer is enabled, it is automatically loaded with the value of *load* register.

When the Timer reaches 0, it is automatically reloaded with value of *reload* register.

The user can latch the current countdown value by writing to *update_value* register, it will update value register with current countdown value.

To use the Timer in One-Shot mode, the user needs to:

- Disable the timer
- Set the load register to the expected duration
- (Re-)Enable the Timer

To use the Timer in Periodic mode, the user needs to:

- Disable the Timer
- Set the load register to 0
- Set the reload register to the expected period
- Enable the Timer

For both modes, the CPU can be advertised by an IRQ that the duration/period has elapsed. (The CPU can also do software polling with `update_value` and `value` to know the elapsed duration)

Register Listing for TIMERO

Register	Address
<i>TIMERO_LOAD</i>	<i>0xf0008000</i>
<i>TIMERO_RELOAD</i>	<i>0xf0008004</i>
<i>TIMERO_EN</i>	<i>0xf0008008</i>
<i>TIMERO_UPDATE_VALUE</i>	<i>0xf000800c</i>
<i>TIMERO_VALUE</i>	<i>0xf0008010</i>
<i>TIMERO_EV_STATUS</i>	<i>0xf0008014</i>
<i>TIMERO_EV_PENDING</i>	<i>0xf0008018</i>
<i>TIMERO_EV_ENABLE</i>	<i>0xf000801c</i>

TIMERO_LOAD

Address: 0xf0008000 + 0x0 = 0xf0008000

Load value when Timer is (re-)enabled. In One-Shot mode, the value written to this register specifies the Timer's duration in clock cycles.

TIMERO_RELOAD

Address: 0xf0008000 + 0x4 = 0xf0008004

Reload value when Timer reaches 0. In Periodic mode, the value written to this register specify the Timer's period in clock cycles.

TIMERO_EN

Address: 0xf0008000 + 0x8 = 0xf0008008

Enable flag of the Timer. Set this flag to 1 to enable/start the Timer. Set to 0 to disable the Timer.

TIMERO_UPDATE_VALUE

Address: 0xf0008000 + 0xc = 0xf000800c

Update trigger for the current countdown value. A write to this register latches the current countdown value to value register.

TIMERO_VALUE

Address: $0xf0008000 + 0x10 = 0xf0008010$

Latched countdown value. This value is updated by writing to `update_value`.

TIMERO_EV_STATUS

Address: $0xf0008000 + 0x14 = 0xf0008014$

This register contains the current raw level of the zero event trigger. Writes to this register have no effect.

Field	Name	Description
[0]	ZERO	Level of the zero event

TIMERO_EV_PENDING

Address: $0xf0008000 + 0x18 = 0xf0008018$

When a zero event occurs, the corresponding bit will be set in this register. To clear the Event, set the corresponding bit in this register.

Field	Name	Description
[0]	ZERO	1 if a <i>zero</i> event occurred. This Event is triggered on a falling edge.

TIMERO_EV_ENABLE

Address: $0xf0008000 + 0x1c = 0xf000801c$

This register enables the corresponding zero events. Write a 0 to this register to disable individual events.

Field	Name	Description
[0]	ZERO	Write a 1 to enable the zero Event

<i>UART_XOVER_TXEMPTY</i>	<i>0xf0008838</i>
<i>UART_XOVER_RXFULL</i>	<i>0xf000883c</i>

UART_RTX

Address: 0xf0008800 + 0x0 = 0xf0008800

UART_TXFULL

Address: 0xf0008800 + 0x4 = 0xf0008804

TX FIFO Full.

UART_RXEMPTY

Address: 0xf0008800 + 0x8 = 0xf0008808

RX FIFO Empty.

UART_EV_STATUS

Address: 0xf0008800 + 0xc = 0xf000880c

This register contains the current raw level of the rx event trigger. Writes to this register have no effect.

Field	Name	Description
[0]	TX	Level of the tx event
[1]	RX	Level of the rx event

UART_EV_PENDING

Address: $0xf0008800 + 0x10 = 0xf0008810$

When a rx event occurs, the corresponding bit will be set in this register. To clear the Event, set the corresponding bit in this register.

Field	Name	Description
[0]	TX	1 if a tx event occurred. This Event is triggered on a falling edge.
[1]	RX	1 if a rx event occurred. This Event is triggered on a falling edge.

UART_EV_ENABLE

Address: $0xf0008800 + 0x14 = 0xf0008814$

This register enables the corresponding rx events. Write a 0 to this register to disable individual events.

Field	Name	Description
[0]	TX	Write a 1 to enable the tx Event
[1]	RX	Write a 1 to enable the rx Event

UART_TXEMPTY

Address: $0xf0008800 + 0x18 = 0xf0008818$

TX FIFO Empty.

UART_RXFULL

Address: $0xf0008800 + 0x1c = 0xf000881c$

RX FIFO Full.

UART_XOVER_RXTX

Address: $0xf0008800 + 0x20 = 0xf0008820$

UART_XOVER_TXFULL

Address: $0xf0008800 + 0x24 = 0xf0008824$

TX FIFO Full.

UART_XOVER_RXEMPTY

Address: $0xf0008800 + 0x28 = 0xf0008828$

RX FIFO Empty.

UART_XOVER_EV_STATUS

Address: $0xf0008800 + 0x2c = 0xf000882c$

This register contains the current raw level of the rx event trigger. Writes to this register have no effect.

Field	Name	Description
[0]	TX	Level of the tx event
[1]	RX	Level of the rx event

UART_XOVER_EV_PENDING

Address: $0xf0008800 + 0x30 = 0xf0008830$

When a rx event occurs, the corresponding bit will be set in this register. To clear the Event, set the corresponding bit in this register.

Field	Name	Description
[0]	TX	1 if a tx event occurred. This Event is triggered on a falling edge.
[1]	RX	1 if a rx event occurred. This Event is triggered on a falling edge.

UART_XOVER_EV_ENABLE

Address: $0xf0008800 + 0x34 = 0xf0008834$

This register enables the corresponding rx events. Write a 0 to this register to disable individual events.

Field	Name	Description
[0]	TX	Write a 1 to enable the tx Event
[1]	RX	Write a 1 to enable the rx Event

UART_XOVER_TXEMPTY

Address: $0xf0008800 + 0x38 = 0xf0008838$

TX FIFO Empty.

UART_XOVER_RXFULL

Address: $0xf0008800 + 0x3c = 0xf000883c$

RX FIFO Full.

DOCUMENTATION FOR ROW HAMMER TESTER LPDDR4 TEST BOARD

16.1 Modules

16.1.1 Interrupt Controller

This device has an EventManager-based interrupt system. Individual modules generate *events* which are wired into a central interrupt controller.

When an interrupt occurs, you should look the interrupt number up in the CPU- specific interrupt table and then call the relevant module.

Assigned Interrupts

The following interrupts are assigned on this system:

Interrupt	Module
1	<i>TIMERO</i>
0	<i>UART</i>

16.2 Register Groups

16.2.5 ROWHAMMER

Row Hammer DMA attacker

This module allows to perform a Row Hammer attack by configuring it with two addresses that map to different rows of a single bank. When enabled, it will perform alternating DMA reads from the given locations, which will result in the DRAM controller having to repeatedly open/close rows at each read access.

Register Listing for ROWHAMMER

Register	Address
<i>ROWHAMMER_ENABLED</i>	<i>0xf0002000</i>
<i>ROWHAMMER_ADDRESS1</i>	<i>0xf0002004</i>
<i>ROWHAMMER_ADDRESS2</i>	<i>0xf0002008</i>
<i>ROWHAMMER_COUNT</i>	<i>0xf000200c</i>

ROWHAMMER_ENABLED

Address: 0xf0002000 + 0x0 = 0xf0002000

Used to start/stop the operation of the module

ROWHAMMER_ADDRESS1

Address: 0xf0002000 + 0x4 = 0xf0002004

First attacked address

ROWHAMMER_ADDRESS2

Address: 0xf0002000 + 0x8 = 0xf0002008

Second attacked address

ROWHAMMER_COUNT

Address: 0xf0002000 + 0xc = 0xf000200c

This is the number of DMA accesses performed. When the module is enabled, the value can be freely read. When the module is disabled, the register is clear-on-write and has to be read before the next attack.

16.2.6 WRITER

DMA DRAM writer.

Allows to fill DRAM with a predefined pattern using DMA.

Pattern

Provides access to RAM to store access pattern: *mem_addr* and *mem_data*. The pattern address space can be limited using the *data_mask*.

For example, having *mem_addr* filled with [*0x04, 0x02, 0x03, ...*] and *mem_data* filled with [*0xff, 0xaa, 0x55, ...*] and setting *data_mask* = *0b01*, the pattern [(address, data), ...] written will be: [(*0x04, 0xff*), (*0x02, 0xaa*), (*0x04, 0xff*), ...] (wraps due to masking).

DRAM memory range that is being accessed can be configured using *mem_mask*.

To use this module, make sure that *ready* is 1, then write the desired number of transfers to *count*. Writing to the *start* CSR will initialize the operation. When the operation is ongoing *ready* will be 0.

Register Listing for WRITER

Register	Address
<i>WRITER_START</i>	<i>0xf0002800</i>
<i>WRITER_READY</i>	<i>0xf0002804</i>

<i>WRITER_INVERTER_DIVISOR_MASK</i>	<i>0xf0002820</i>
<i>WRITER_INVERTER_SELECTION_MASK</i>	<i>0xf0002824</i>
<i>WRITER_LAST_ADDRESS</i>	<i>0xf0002828</i>

WRITER_START

Address: $0xf0002800 + 0x0 = 0xf0002800$

Write to the register starts the transfer (if ready=1)

WRITER_READY

Address: $0xf0002800 + 0x4 = 0xf0002804$

Indicates that the transfer is not ongoing

WRITER_MODULO

Address: $0xf0002800 + 0x8 = 0xf0002808$

When set use modulo to calculate DMA transfers address rather than bit masking

WRITER_COUNT

Address: $0xf0002800 + 0xc = 0xf000280c$

Desired number of DMA transfers

WRITER_DONE

Address: $0xf0002800 + 0x10 = 0xf0002810$

Number of completed DMA transfers

WRITER_MEM_MASK

Address: $0xf0002800 + 0x14 = 0xf0002814$

DRAM address mask for DMA transfers

WRITER_DATA_MASK

Address: $0xf0002800 + 0x18 = 0xf0002818$

Pattern memory address mask

WRITER_DATA_DIV

Address: $0xf0002800 + 0x1c = 0xf000281c$

Pattern memory address divisor-1

WRITER_INVERTER_DIVISOR_MASK

Address: $0xf0002800 + 0x20 = 0xf0002820$

Divisor mask for selecting rows for which pattern data gets inverted

WRITER_INVERTER_SELECTION_MASK

Address: $0xf0002800 + 0x24 = 0xf0002824$

Selection mask for selecting rows for which pattern data gets inverted

WRITER_LAST_ADDRESS

Address: $0xf0002800 + 0x28 = 0xf0002828$

Number of completed DMA transfers

16.2.7 READER

DMA DRAM reader.

Allows to check DRAM contents against a predefined pattern using DMA.

Pattern

Provides access to RAM to store access pattern: *mem_addr* and *mem_data*. The pattern address space can be limited using the *data_mask*.

For example, having *mem_addr* filled with $[0x04, 0x02, 0x03, \dots]$ and *mem_data* filled with $[0xff, 0xaa, 0x55, \dots]$ and setting *data_mask* = $0b01$, the pattern [(address, data), ...] written will be: $[(0x04, 0xff), (0x02, 0xaa), (0x04, 0xff), \dots]$ (wraps due to masking).

DRAM memory range that is being accessed can be configured using *mem_mask*.

To use this module, make sure that *ready* is 1, then write the desired number of transfers to *count*. Writing to the *start* CSR will initialize the operation. When the operation is ongoing *ready* will be 0.

Reading errors

This module allows to check the locations of errors in the memory. It scans the configured memory area and compares the values read to the predefined pattern. If *skip_fifo* is 0, this module will stop after each error encountered, so that it can be examined. Wait until the *error_ready* CSR is 1. Then use the CSRs *error_offset*, *error_data* and *error_expected* to examine the errors in the current transfer. To continue reading, write 1 to *error_continue* CSR. Setting *skip_fifo* to 1 will disable this behaviour entirely.

The final number of errors can be read from *error_count*. NOTE: This value represents the number of erroneous *DMA transfers*.

The current progress can be read from the *done* CSR.

Address: $0xf0003000 + 0x70 = 0xf0003070$

Bits 0-31 of *READER_ERROR_EXPECTED*.

READER_ERROR_READY

Address: $0xf0003000 + 0x74 = 0xf0003074$

Error detected and ready to read

READER_ERROR_CONTINUE

Address: $0xf0003000 + 0x78 = 0xf0003078$

Continue reading until the next error

16.2.8 DFI_SWITCH

Register Listing for DFI_SWITCH

Register	Address
<i>DFI_SWITCH_REFRESH_COUNT</i>	<i>0xf0003800</i>
<i>DFI_SWITCH_AT_REFRESH</i>	<i>0xf0003804</i>
<i>DFI_SWITCH_REFRESH_UPDATE</i>	<i>0xf0003808</i>

DFI_SWITCH_REFRESH_COUNT

Address: $0xf0003800 + 0x0 = 0xf0003800$

Count of all refresh commands issued (both by Memory Controller and Payload Executor). Value is latched from internal counter on mode transition: MC -> PE or by writing to the *refresh_update* CSR.

DFI_SWITCH_AT_REFRESH

Address: $0xf0003800 + 0x4 = 0xf0003804$

If set to a value different than 0 the mode transition MC -> PE will be performed only when the value of this register matches the current refresh commands count.

DFI_SWITCH_REFRESH_UPDATE

Address: $0xf0003800 + 0x8 = 0xf0003808$

Force an update of the *refresh_count* CSR.

16.2.9 PAYLOAD_EXECUTOR

Executes the DRAM payload from memory

Instruction decoder

All instructions are 32-bit. The format of most instructions is the same, except for the LOOP instruction, which has a constant TIMESLICE of 1.

NOOP with a TIMESLICE of 0 is a special case which is interpreted as STOP instruction. When this instruction is encountered execution gets finished immediately.

NOTE: TIMESLICE is the number of cycles the instruction will take. This means that instructions other than NOOP that use TIMESLICE=0 are illegal (although will silently be executed as having TIMESLICE=1).

NOTE2: LOOP instruction will *jump* COUNT times, meaning that the “code” inside the loop will effectively be executed COUNT+1 times.

Op codes:

Op	Value
NOOP	0b000
LOOP	0b111
ACT	0b100
PRE	0b101
REF	0b110
ZQC	0b001
READ	0b010

Instruction format:

	LSB		MSB
dfi:	OP_CODE		TIMESLICE ADDRESS
noop:	OP_CODE		TIMESLICE_NOOP
loop:	OP_CODE		COUNT JUMP
stop:	<NOOP>		0

Where ADDRESS depends on the DFI command and is one of:

	LSB		MSB
	RANK		BANK COLUMN
	RANK		BANK ROW

SDRAM_DFII_CONTROL

Address: $0xf0006000 + 0x0 = 0xf0006000$

Control DFI signals common to all phases

Field	Name	Description						
[0]	SEL	<table border="1"> <thead> <tr> <th>Value</th> <th>Description</th> </tr> </thead> <tbody> <tr> <td>0b0</td> <td>Software (CPU) control.</td> </tr> <tr> <td>0b1</td> <td>Hardware control (default).</td> </tr> </tbody> </table>	Value	Description	0b0	Software (CPU) control.	0b1	Hardware control (default).
Value	Description							
0b0	Software (CPU) control.							
0b1	Hardware control (default).							
[1]	CKE	DFI clock enable bus						
[2]	ODT	DFI on-die termination bus						
[3]	RESET_N	DFI clock reset bus						

SDRAM_DFII_PIO_COMMAND

Address: $0xf0006000 + 0x4 = 0xf0006004$

Control DFI signals on a single phase

Field	Name	Description
[0]	CS	DFI chip select bus
[1]	WE	DFI write enable bus
[2]	CAS	DFI column address strobe bus
[3]	RAS	DFI row address strobe bus
[4]	WREN	DFI write data enable bus
[5]	RDEN	DFI read data enable bus

16.2.16 TIMERO

Timer

Provides a generic Timer core.

The Timer is implemented as a countdown timer that can be used in various modes:

- Polling : Returns current countdown value to software
- One-Shot: Loads itself and stops when value reaches 0
- Periodic: (Re-)Loads itself when value reaches 0

en register allows the user to enable/disable the Timer. When the Timer is enabled, it is automatically loaded with the value of *load* register.

When the Timer reaches 0, it is automatically reloaded with value of *reload* register.

The user can latch the current countdown value by writing to *update_value* register, it will update *value* register with current countdown value.

To use the Timer in One-Shot mode, the user needs to:

- Disable the timer

- Set the load register to the expected duration
- (Re-)Enable the Timer

To use the Timer in Periodic mode, the user needs to:

- Disable the Timer
- Set the load register to 0
- Set the reload register to the expected period
- Enable the Timer

For both modes, the CPU can be advertised by an IRQ that the duration/period has elapsed. (The CPU can also do software polling with `update_value` and `value` to know the elapsed duration)

Register Listing for TIMERO

Register	Address
<i>TIMERO_LOAD</i>	<i>0xf0007800</i>
<i>TIMERO_RELOAD</i>	<i>0xf0007804</i>
<i>TIMERO_EN</i>	<i>0xf0007808</i>
<i>TIMERO_UPDATE_VALUE</i>	<i>0xf000780c</i>
<i>TIMERO_VALUE</i>	<i>0xf0007810</i>
<i>TIMERO_EV_STATUS</i>	<i>0xf0007814</i>
<i>TIMERO_EV_PENDING</i>	<i>0xf0007818</i>
<i>TIMERO_EV_ENABLE</i>	<i>0xf000781c</i>

TIMERO_LOAD

Address: 0xf0007800 + 0x0 = 0xf0007800

Load value when Timer is (re-)enabled. In One-Shot mode, the value written to this register specifies the Timer's duration in clock cycles.

TIMERO_RELOAD

Address: 0xf0007800 + 0x4 = 0xf0007804

Reload value when Timer reaches 0. In Periodic mode, the value written to this register specify the Timer's period in clock cycles.

TIMERO_EN

Address: $0xf0007800 + 0x8 = 0xf0007808$

Enable flag of the Timer. Set this flag to 1 to enable/start the Timer. Set to 0 to disable the Timer.

TIMERO_UPDATE_VALUE

Address: $0xf0007800 + 0xc = 0xf000780c$

Update trigger for the current countdown value. A write to this register latches the current countdown value to value register.

TIMERO_VALUE

Address: $0xf0007800 + 0x10 = 0xf0007810$

Latched countdown value. This value is updated by writing to update_value.

TIMERO_EV_STATUS

Address: $0xf0007800 + 0x14 = 0xf0007814$

This register contains the current raw level of the zero event trigger. Writes to this register have no effect.

Field	Name	Description
[0]	ZERO	Level of the zero event

TIMERO_EV_PENDING

Address: $0xf0007800 + 0x18 = 0xf0007818$

When a zero event occurs, the corresponding bit will be set in this register. To clear the Event, set the corresponding bit in this register.

Field	Name	Description
[0]	ZERO	1 if a zero event occurred. This Event is triggered on a falling edge.

TIMERO_EV_ENABLE

Address: $0xf0007800 + 0x1c = 0xf000781c$

This register enables the corresponding zero events. Write a 0 to this register to disable individual events.

Field	Name	Description
[0]	ZERO	Write a 1 to enable the zero Event

16.2.17 UART

Register Listing for UART

<i>UART_XOVER_TXEMPTY</i>	<i>0xf0008038</i>
<i>UART_XOVER_RXFULL</i>	<i>0xf000803c</i>

UART_RXTX

Address: $0xf0008000 + 0x0 = 0xf0008000$

UART_TXFULL

Address: $0xf0008000 + 0x4 = 0xf0008004$

TX FIFO Full.

UART_RXEMPTY

Address: $0xf0008000 + 0x8 = 0xf0008008$

RX FIFO Empty.

UART_EV_STATUS

Address: $0xf0008000 + 0xc = 0xf000800c$

This register contains the current raw level of the rx event trigger. Writes to this register have no effect.

Field	Name	Description
[0]	TX	Level of the tx event
[1]	RX	Level of the rx event

UART_EV_PENDING

Address: $0xf0008000 + 0x10 = 0xf0008010$

When a rx event occurs, the corresponding bit will be set in this register. To clear the Event, set the corresponding bit in this register.

Field	Name	Description
[0]	TX	1 if a tx event occurred. This Event is triggered on a falling edge.
[1]	RX	1 if a rx event occurred. This Event is triggered on a falling edge.

UART_EV_ENABLE

Address: $0xf0008000 + 0x14 = 0xf0008014$

This register enables the corresponding rx events. Write a 0 to this register to disable individual events.

Field	Name	Description
[0]	TX	Write a 1 to enable the tx Event
[1]	RX	Write a 1 to enable the rx Event

UART_TXEMPTY

Address: $0xf0008000 + 0x18 = 0xf0008018$

TX FIFO Empty.

UART_RXFULL

Address: $0xf0008000 + 0x1c = 0xf000801c$

RX FIFO Full.

UART_XOVER_RXTX

Address: $0xf0008000 + 0x20 = 0xf0008020$

UART_XOVER_TXFULL

Address: $0xf0008000 + 0x24 = 0xf0008024$

TX FIFO Full.

UART_XOVER_RXEMPTY

Address: $0xf0008000 + 0x28 = 0xf0008028$

RX FIFO Empty.

UART_XOVER_EV_STATUS

Address: $0xf0008000 + 0x2c = 0xf000802c$

This register contains the current raw level of the rx event trigger. Writes to this register have no effect.

Field	Name	Description
[0]	TX	Level of the tx event
[1]	RX	Level of the rx event

UART_XOVER_EV_PENDING

Address: $0xf0008000 + 0x30 = 0xf0008030$

When a rx event occurs, the corresponding bit will be set in this register. To clear the Event, set the corresponding bit in this register.

Field	Name	Description
[0]	TX	1 if a tx event occurred. This Event is triggered on a falling edge.
[1]	RX	1 if a rx event occurred. This Event is triggered on a falling edge.

UART_XOVER_EV_ENABLE

Address: $0xf0008000 + 0x34 = 0xf0008034$

This register enables the corresponding rx events. Write a 0 to this register to disable individual events.

Field	Name	Description
[0]	TX	Write a 1 to enable the tx Event
[1]	RX	Write a 1 to enable the rx Event

UART_XOVER_TXEMPTY

Address: $0xf0008000 + 0x38 = 0xf0008038$

TX FIFO Empty.

UART_XOVER_RXFULL

Address: 0xf0008000 + 0x3c = 0xf000803c

RX FIFO Full.

DOCUMENTATION FOR ROW HAMMER TESTER DDR5 TEST
BOARD

17.1 Modules

17.1.1 Interrupt Controller

This device has an EventManager-based interrupt system. Individual modules generate *events* which are wired into a central interrupt controller.

When an interrupt occurs, you should look the interrupt number up in the CPU- specific interrupt table and then call the relevant module.

Assigned Interrupts

The following interrupts are assigned on this system:

Interrupt	Module
1	<i>TIMERO</i>
0	<i>UART</i>

17.2.3 CONTROLLER_SETTINGS

Allows to change LiteDRAMController behaviour at runtime

Register Listing for CONTROLLER_SETTINGS

Register	Address
<i>CONTROLLER_SETTINGS_REFRESH</i>	<i>0xf0001000</i>

CONTROLLER_SETTINGS_REFRESH

Address: $0xf0001000 + 0x0 = 0xf0001000$

Enable/disable Refresh commands sending

17.2.4 DDRCTRL

Register Listing for DDRCTRL

Register	Address
<i>DDRCTRL_INIT_DONE</i>	<i>0xf0001800</i>
<i>DDRCTRL_INIT_ERROR</i>	<i>0xf0001804</i>

DDRCTRL_INIT_DONE

Address: $0xf0001800 + 0x0 = 0xf0001800$

DDRCTRL_INIT_ERROR

Address: $0xf0001800 + 0x4 = 0xf0001804$

17.2.5 ROWHAMMER

Row Hammer DMA attacker

This module allows to perform a Row Hammer attack by configuring it with two addresses that map to different rows of a single bank. When enabled, it will perform alternating DMA reads from the given locations, which will result in the DRAM controller having to repeatedly open/close rows at each read access.

Register Listing for ROWHAMMER

Register	Address
<i>ROWHAMMER_ENABLED</i>	<i>0xf0002000</i>
<i>ROWHAMMER_ADDRESS1</i>	<i>0xf0002004</i>
<i>ROWHAMMER_ADDRESS2</i>	<i>0xf0002008</i>
<i>ROWHAMMER_COUNT</i>	<i>0xf000200c</i>

ROWHAMMER_ENABLED

Address: 0xf0002000 + 0x0 = 0xf0002000

Used to start/stop the operation of the module

ROWHAMMER_ADDRESS1

Address: 0xf0002000 + 0x4 = 0xf0002004

First attacked address

ROWHAMMER_ADDRESS2

Address: 0xf0002000 + 0x8 = 0xf0002008

Second attacked address

ROWHAMMER_COUNT

Address: 0xf0002000 + 0xc = 0xf000200c

This is the number of DMA accesses performed. When the module is enabled, the value can be freely read. When the module is disabled, the register is clear-on-write and has to be read before the next attack.

17.2.6 WRITER

DMA DRAM writer.

Allows to fill DRAM with a predefined pattern using DMA.

Pattern

Provides access to RAM to store access pattern: *mem_addr* and *mem_data*. The pattern address space can be limited using the *data_mask*.

For example, having *mem_addr* filled with [0x04, 0x02, 0x03, ...] and *mem_data* filled with [0xff, 0xaa, 0x55, ...] and setting *data_mask* = 0b01, the pattern [(address, data), ...] written will be: [(0x04, 0xff), (0x02, 0xaa), (0x04, 0xff), ...] (wraps due to masking).

DRAM memory range that is being accessed can be configured using *mem_mask*.

To use this module, make sure that *ready* is 1, then write the desired number of transfers to *count*. Writing to the *start* CSR will initialize the operation. When the operation is ongoing *ready* will be 0.

Register Listing for WRITER

Register	Address
<i>WRITER_START</i>	0xf0002800
<i>WRITER_READY</i>	0xf0002804
<i>WRITER_MODULO</i>	0xf0002808
<i>WRITER_COUNT</i>	0xf000280c
<i>WRITER_DONE</i>	0xf0002810
<i>WRITER_MEM_MASK</i>	0xf0002814
<i>WRITER_DATA_MASK</i>	0xf0002818
<i>WRITER_DATA_DIV</i>	0xf000281c
<i>WRITER_INVERTER_DIVISOR_MASK</i>	0xf0002820
<i>WRITER_INVERTER_SELECTION_MASK</i>	0xf0002824
<i>WRITER_LAST_ADDRESS</i>	0xf0002828

WRITER_START

Address: $0xf0002800 + 0x0 = 0xf0002800$

Write to the register starts the transfer (if ready=1)

WRITER_READY

Address: $0xf0002800 + 0x4 = 0xf0002804$

Indicates that the transfer is not ongoing

WRITER_MODULO

Address: $0xf0002800 + 0x8 = 0xf0002808$

When set use modulo to calculate DMA transfers address rather than bit masking

WRITER_COUNT

Address: $0xf0002800 + 0xc = 0xf000280c$

Desired number of DMA transfers

WRITER_DONE

Address: $0xf0002800 + 0x10 = 0xf0002810$

Number of completed DMA transfers

WRITER_MEM_MASK

Address: $0xf0002800 + 0x14 = 0xf0002814$

DRAM address mask for DMA transfers

WRITER_DATA_MASK

Address: $0xf0002800 + 0x18 = 0xf0002818$

Pattern memory address mask

WRITER_DATA_DIV

Address: $0xf0002800 + 0x1c = 0xf000281c$

Pattern memory address divisor-1

WRITER_INVERTER_DIVISOR_MASK

Address: $0xf0002800 + 0x20 = 0xf0002820$

Divisor mask for selecting rows for which pattern data gets inverted

WRITER_INVERTER_SELECTION_MASK

Address: $0xf0002800 + 0x24 = 0xf0002824$

Selection mask for selecting rows for which pattern data gets inverted

WRITER_LAST_ADDRESS

Address: $0xf0002800 + 0x28 = 0xf0002828$

Number of completed DMA transfers

17.2.7 READER

DMA DRAM reader.

Allows to check DRAM contents against a predefined pattern using DMA.

Pattern

Provides access to RAM to store access pattern: *mem_addr* and *mem_data*. The pattern address space can be limited using the *data_mask*.

For example, having *mem_addr* filled with $[0x04, 0x02, 0x03, \dots]$ and *mem_data* filled with $[0xff, 0xaa, 0x55, \dots]$ and setting *data_mask* = $0b01$, the pattern [(address, data), ...] written will be: $[(0x04, 0xff), (0x02, 0xaa), (0x04, 0xff), \dots]$ (wraps due to masking).

DRAM memory range that is being accessed can be configured using *mem_mask*.

To use this module, make sure that *ready* is 1, then write the desired number of transfers to *count*. Writing to the *start* CSR will initialize the operation. When the operation is ongoing *ready* will be 0.

Reading errors

This module allows to check the locations of errors in the memory. It scans the configured memory area and compares the values read to the predefined pattern. If *skip_fifo* is 0, this module will stop after each error encountered, so that it can be examined. Wait until the *error_ready* CSR is 1. Then use the CSRs *error_offset*, *error_data* and *error_expected* to examine the errors in the current transfer. To continue reading, write 1 to *error_continue* CSR. Setting *skip_fifo* to 1 will disable this behaviour entirely.

The final number of errors can be read from *error_count*. NOTE: This value represents the number of erroneous *DMA transfers*.

The current progress can be read from the *done* CSR.

<i>READER_ERROR_CONTINUE</i>	<i>0xf0003048</i>

READER_START

Address: $0xf0003000 + 0x0 = 0xf0003000$

Write to the register starts the transfer (if ready=1)

READER_READY

Address: $0xf0003000 + 0x4 = 0xf0003004$

Indicates that the transfer is not ongoing

READER_MODULO

Address: $0xf0003000 + 0x8 = 0xf0003008$

When set use modulo to calculate DMA transfers address rather than bit masking

READER_COUNT

Address: 0xf0003000 + 0xc = 0xf000300c

Desired number of DMA transfers

READER_DONE

Address: 0xf0003000 + 0x10 = 0xf0003010

Number of completed DMA transfers

READER_MEM_MASK

Address: 0xf0003000 + 0x14 = 0xf0003014

DRAM address mask for DMA transfers

READER_DATA_MASK

Address: 0xf0003000 + 0x18 = 0xf0003018

Pattern memory address mask

READER_DATA_DIV

Address: 0xf0003000 + 0x1c = 0xf000301c

Pattern memory address divisor-1

READER_INVERTER_DIVISOR_MASK

Address: 0xf0003000 + 0x20 = 0xf0003020

Divisor mask for selecting rows for which pattern data gets inverted

READER_INVERTER_SELECTION_MASK

Address: 0xf0003000 + 0x24 = 0xf0003024

Selection mask for selecting rows for which pattern data gets inverted

READER_ERROR_COUNT

Address: $0xf0003000 + 0x28 = 0xf0003028$

Number of errors detected

READER_SKIP_FIFO

Address: $0xf0003000 + 0x2c = 0xf000302c$

Skip waiting for user to read the errors FIFO

READER_ERROR_OFFSET

Address: $0xf0003000 + 0x30 = 0xf0003030$

Current offset of the error

READER_ERROR_DATA1

Address: $0xf0003000 + 0x34 = 0xf0003034$

Bits 32-63 of *READER_ERROR_DATA*. Erroneous value read from DRAM memory

READER_ERROR_DATA0

Address: $0xf0003000 + 0x38 = 0xf0003038$

Bits 0-31 of *READER_ERROR_DATA*.

READER_ERROR_EXPECTED1

Address: $0xf0003000 + 0x3c = 0xf000303c$

Bits 32-63 of *READER_ERROR_EXPECTED*. Value expected to be read from DRAM memory

READER_ERROR_EXPECTED0

Address: $0xf0003000 + 0x40 = 0xf0003040$

Bits 0-31 of *READER_ERROR_EXPECTED*.

READER_ERROR_READY

Address: $0xf0003000 + 0x44 = 0xf0003044$

Error detected and ready to read

READER_ERROR_CONTINUE

Address: $0xf0003000 + 0x48 = 0xf0003048$

Continue reading until the next error

17.2.8 DFI_SWITCH

Register Listing for DFI_SWITCH

Register	Address
<i>DFI_SWITCH_REFRESH_COUNT</i>	<i>0xf0003800</i>
<i>DFI_SWITCH_AT_REFRESH</i>	<i>0xf0003804</i>
<i>DFI_SWITCH_REFRESH_UPDATE</i>	<i>0xf0003808</i>

DFI_SWITCH_REFRESH_COUNT

Address: $0xf0003800 + 0x0 = 0xf0003800$

Count of all refresh commands issued (both by Memory Controller and Payload Executor). Value is latched from internal counter on mode transition: MC -> PE or by writing to the *refresh_update* CSR.

DFI_SWITCH_AT_REFRESH

Address: $0xf0003800 + 0x4 = 0xf0003804$

If set to a value different than 0 the mode transition MC -> PE will be performed only when the value of this register matches the current refresh commands count.

DFI_SWITCH_REFRESH_UPDATE

Address: $0xf0003800 + 0x8 = 0xf0003808$

Force an update of the *refresh_count* CSR.

17.2.9 PAYLOAD_EXECUTOR

Executes the DRAM payload from memory

Instruction decoder

All instructions are 32-bit. The format of most instructions is the same, except for the LOOP instruction, which has a constant TIMESLICE of 1.

NOOP with a TIMESLICE of 0 is a special case which is interpreted as STOP instruction. When this instruction is encountered execution gets finished immediately.

NOTE: TIMESLICE is the number of cycles the instruction will take. This means that instructions other than NOOP that use TIMESLICE=0 are illegal (although will silently be executed as having TIMESLICE=1).

NOTE2: LOOP instruction will *jump* COUNT times, meaning that the “code” inside the loop will effectively be executed COUNT+1 times.

Op codes:

Op	Value
NOOP	0b000
LOOP	0b111
ACT	0b100
PRE	0b101
REF	0b110
ZQC	0b001
READ	0b010

Instruction format:

	LSB		MSB
dfi:	OP_CODE		TIMESLICE ADDRESS
noop:	OP_CODE		TIMESLICE_NOOP
loop:	OP_CODE		COUNT JUMP
stop:	<NOOP>		0

Where ADDRESS depends on the DFI command and is one of:

	LSB		MSB
	RANK		BANK COLUMN
	RANK		BANK ROW

Register Listing for PAYLOAD_EXECUTOR

Register	Address
<i>PAYLOAD_EXECUTOR_START</i>	<i>0xf0004000</i>
<i>PAYLOAD_EXECUTOR_STATUS</i>	<i>0xf0004004</i>
<i>PAYLOAD_EXECUTOR_READ_COUNT</i>	<i>0xf0004008</i>

PAYLOAD_EXECUTOR_START

Address: $0xf0004000 + 0x0 = 0xf0004000$

Writing to this register initializes payload execution

PAYLOAD_EXECUTOR_STATUS

Address: $0xf0004000 + 0x4 = 0xf0004004$

Payload executor status register

Field Name	Description
[0] READY	Indicates that the executor is not running
[1] OVER-FLOW	Indicates the scratchpad memory address counter has overflowed due to the number of READ commands sent during execution

PAYLOAD_EXECUTOR_READ_COUNT

Address: $0xf0004000 + 0x8 = 0xf0004008$

Number of data from READ commands that is stored in the scratchpad memory

17.2.10 CTRL

Register Listing for CTRL

Register	Address
<i>CTRL_RESET</i>	<i>0xf0004800</i>
<i>CTRL_SCRATCH</i>	<i>0xf0004804</i>
<i>CTRL_BUS_ERRORS</i>	<i>0xf0004808</i>

CTRL__RESET

Address: $0xf0004800 + 0x0 = 0xf0004800$

Field	Name	Description
[0]	SOC_RST	Write 1 to this register to reset the full SoC (Pulse Reset)
[1]	CPU_RST	Write 1 to this register to reset the CPU(s) of the SoC (Hold Reset)

CTRL_SCRATCH

Address: $0xf0004800 + 0x4 = 0xf0004804$

Use this register as a scratch space to verify that software read/write accesses to the Wishbone/CSR bus are working correctly. The initial reset value of 0x1234578 can be used to verify endianness.

CTRL_BUS_ERRORS

Address: $0xf0004800 + 0x8 = 0xf0004808$

Total number of Wishbone bus errors (timeouts) since start.

17.2.17 TIMERO

Timer

Provides a generic Timer core.

The Timer is implemented as a countdown timer that can be used in various modes:

- Polling : Returns current countdown value to software
- One-Shot: Loads itself and stops when value reaches 0
- Periodic: (Re-)Loads itself when value reaches 0

en register allows the user to enable/disable the Timer. When the Timer is enabled, it is automatically loaded with the value of *load* register.

When the Timer reaches 0, it is automatically reloaded with value of *reload* register.

The user can latch the current countdown value by writing to *update_value* register, it will update value register with current countdown value.

To use the Timer in One-Shot mode, the user needs to:

- Disable the timer
- Set the load register to the expected duration
- (Re-)Enable the Timer

To use the Timer in Periodic mode, the user needs to:

- Disable the Timer
- Set the load register to 0
- Set the reload register to the expected period
- Enable the Timer

For both modes, the CPU can be advertised by an IRQ that the duration/period has elapsed. (The CPU can also do software polling with *update_value* and *value* to know the elapsed duration)

Register Listing for TIMERO

Register	Address
<i>TIMERO_LOAD</i>	<i>0xf0008000</i>
<i>TIMERO_RELOAD</i>	<i>0xf0008004</i>
<i>TIMERO_EN</i>	<i>0xf0008008</i>
<i>TIMERO_UPDATE_VALUE</i>	<i>0xf000800c</i>
<i>TIMERO_VALUE</i>	<i>0xf0008010</i>
<i>TIMERO_EV_STATUS</i>	<i>0xf0008014</i>
<i>TIMERO_EV_PENDING</i>	<i>0xf0008018</i>
<i>TIMERO_EV_ENABLE</i>	<i>0xf000801c</i>

TIMERO_LOAD

Address: $0xf0008000 + 0x0 = 0xf0008000$

Load value when Timer is (re-)enabled. In One-Shot mode, the value written to this register specifies the Timer's duration in clock cycles.

TIMERO_RELOAD

Address: $0xf0008000 + 0x4 = 0xf0008004$

Reload value when Timer reaches 0. In Periodic mode, the value written to this register specify the Timer's period in clock cycles.

TIMERO_EN

Address: $0xf0008000 + 0x8 = 0xf0008008$

Enable flag of the Timer. Set this flag to 1 to enable/start the Timer. Set to 0 to disable the Timer.

TIMERO_UPDATE_VALUE

Address: $0xf0008000 + 0xc = 0xf000800c$

Update trigger for the current countdown value. A write to this register latches the current countdown value to value register.

TIMERO_VALUE

Address: $0xf0008000 + 0x10 = 0xf0008010$

Latched countdown value. This value is updated by writing to update_value.

TIMERO_EV_STATUS

Address: $0xf0008000 + 0x14 = 0xf0008014$

This register contains the current raw level of the zero event trigger. Writes to this register have no effect.

Field	Name	Description
[0]	ZERO	Level of the zero event

TIMERO_EV_PENDING

Address: $0xf0008000 + 0x18 = 0xf0008018$

When a zero event occurs, the corresponding bit will be set in this register. To clear the Event, set the corresponding bit in this register.

Field	Name	Description
[0]	ZERO	1 if a <i>zero</i> event occurred. This Event is triggered on a falling edge.

TIMERO_EV_ENABLE

Address: $0xf0008000 + 0x1c = 0xf000801c$

This register enables the corresponding zero events. Write a 0 to this register to disable individual events.

Field	Name	Description
[0]	ZERO	Write a 1 to enable the zero Event

UART_TXFULL

Address: $0xf0008800 + 0x4 = 0xf0008804$

TX FIFO Full.

UART_RXEMPTY

Address: $0xf0008800 + 0x8 = 0xf0008808$

RX FIFO Empty.

UART_EV_STATUS

Address: $0xf0008800 + 0xc = 0xf000880c$

This register contains the current raw level of the rx event trigger. Writes to this register have no effect.

Field	Name	Description
[0]	TX	Level of the tx event
[1]	RX	Level of the rx event

UART_EV_PENDING

Address: $0xf0008800 + 0x10 = 0xf0008810$

When a rx event occurs, the corresponding bit will be set in this register. To clear the Event, set the corresponding bit in this register.

Field	Name	Description
[0]	TX	1 if a tx event occurred. This Event is triggered on a falling edge.
[1]	RX	1 if a rx event occurred. This Event is triggered on a falling edge.

UART_EV_ENABLE

Address: $0xf0008800 + 0x14 = 0xf0008814$

This register enables the corresponding rx events. Write a 0 to this register to disable individual events.

Field	Name	Description
[0]	TX	Write a 1 to enable the tx Event
[1]	RX	Write a 1 to enable the rx Event

UART_TXEMPTY

Address: $0xf0008800 + 0x18 = 0xf0008818$

TX FIFO Empty.

UART_RXFULL

Address: $0xf0008800 + 0x1c = 0xf000881c$

RX FIFO Full.

UART_XOVER_RXTX

Address: $0xf0008800 + 0x20 = 0xf0008820$

UART_XOVER_TXFULL

Address: $0xf0008800 + 0x24 = 0xf0008824$

TX FIFO Full.

UART_XOVER_RXEMPTY

Address: $0xf0008800 + 0x28 = 0xf0008828$

RX FIFO Empty.

UART_XOVER_EV_STATUS

Address: $0xf0008800 + 0x2c = 0xf000882c$

This register contains the current raw level of the rx event trigger. Writes to this register have no effect.

Field	Name	Description
[0]	TX	Level of the tx event
[1]	RX	Level of the rx event

UART_XOVER_EV_PENDING

Address: $0xf0008800 + 0x30 = 0xf0008830$

When a rx event occurs, the corresponding bit will be set in this register. To clear the Event, set the corresponding bit in this register.

Field	Name	Description
[0]	TX	1 if a tx event occurred. This Event is triggered on a falling edge.
[1]	RX	1 if a rx event occurred. This Event is triggered on a falling edge.

UART_XOVER_EV_ENABLE

Address: $0xf0008800 + 0x34 = 0xf0008834$

This register enables the corresponding rx events. Write a 0 to this register to disable individual events.

Field	Name	Description
[0]	TX	Write a 1 to enable the tx Event
[1]	RX	Write a 1 to enable the rx Event

UART_XOVER_TXEMPTY

Address: $0xf0008800 + 0x38 = 0xf0008838$

TX FIFO Empty.

UART_XOVER_RXFULL

Address: 0xf0008800 + 0x3c = 0xf000883c

RX FIFO Full.

DOCUMENTATION FOR ROW HAMMER TESTER DDR5 TESTER

18.1 Modules

18.1.1 Interrupt Controller

This device has an EventManager-based interrupt system. Individual modules generate *events* which are wired into a central interrupt controller.

When an interrupt occurs, you should look the interrupt number up in the CPU- specific interrupt table and then call the relevant module.

Assigned Interrupts

The following interrupts are assigned on this system:

Interrupt	Module
1	<i>TIMERO</i>
0	<i>UART</i>

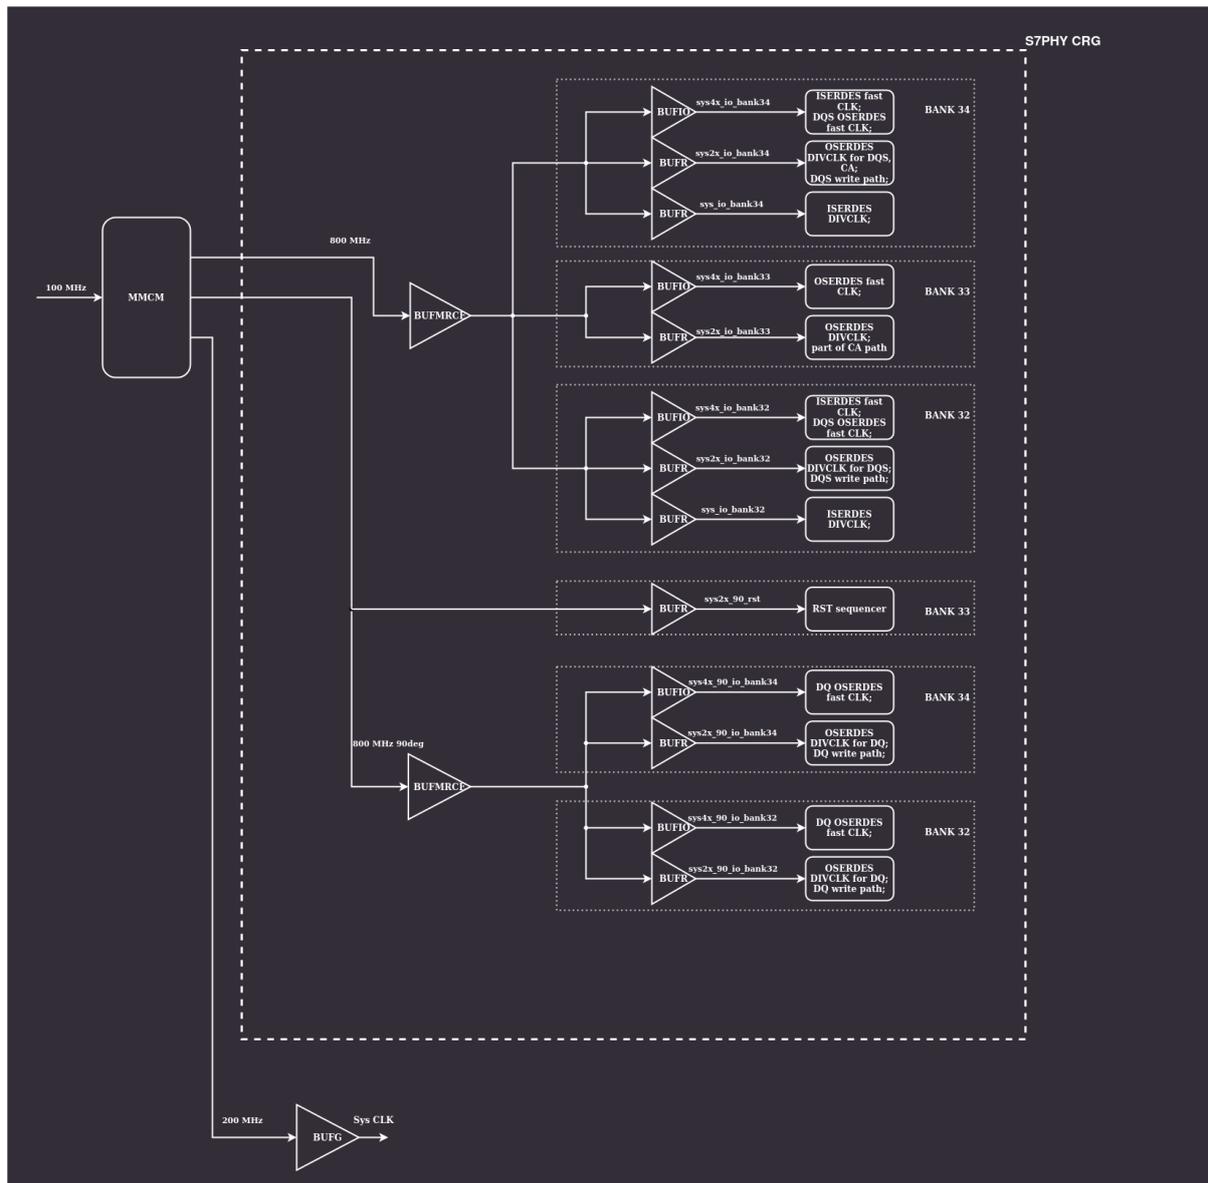

18.1.2 PHYCRG

S7CRGPHY

This module contains 7 series specific clock and reset generation for S7DDR5 PHY. It adds:

- BUFMRCE to control multi region PHYs (UDIMMs and/or RDIMMs),
- BUFMRCE/BUFRs reset sequence,
- ISERDES reset sequence correct with Xilinx documentation and design advisories,
- OSERDES reset sequence.

18.2.3 CONTROLLER_SETTINGS

Allows to change LiteDRAMController behaviour at runtime

Register Listing for CONTROLLER_SETTINGS

Register	Address
<i>CONTROLLER_SETTINGS_REFRESH</i>	<i>0xf0001000</i>

CONTROLLER_SETTINGS_REFRESH

Address: $0xf0001000 + 0x0 = 0xf0001000$

Enable/disable Refresh commands sending

18.2.4 DDRCTRL

Register Listing for DDRCTRL

Register	Address
<i>DDRCTRL_INIT_DONE</i>	<i>0xf0001800</i>
<i>DDRCTRL_INIT_ERROR</i>	<i>0xf0001804</i>

DDRCTRL_INIT_DONE

Address: $0xf0001800 + 0x0 = 0xf0001800$

DDRCTRL_INIT_ERROR

Address: $0xf0001800 + 0x4 = 0xf0001804$

18.2.5 ROWHAMMER

Row Hammer DMA attacker

This module allows to perform a Row Hammer attack by configuring it with two addresses that map to different rows of a single bank. When enabled, it will perform alternating DMA reads from the given locations, which will result in the DRAM controller having to repeatedly open/close rows at each read access.

Register Listing for ROWHAMMER

Register	Address
<i>ROWHAMMER_ENABLED</i>	<i>0xf0002000</i>
<i>ROWHAMMER_ADDRESS1</i>	<i>0xf0002004</i>
<i>ROWHAMMER_ADDRESS2</i>	<i>0xf0002008</i>
<i>ROWHAMMER_COUNT</i>	<i>0xf000200c</i>

ROWHAMMER_ENABLED

Address: $0xf0002000 + 0x0 = 0xf0002000$

Used to start/stop the operation of the module

ROWHAMMER_ADDRESS1

Address: $0xf0002000 + 0x4 = 0xf0002004$

First attacked address

ROWHAMMER_ADDRESS2

Address: $0xf0002000 + 0x8 = 0xf0002008$

Second attacked address

ROWHAMMER_COUNT

Address: $0xf0002000 + 0xc = 0xf000200c$

This is the number of DMA accesses performed. When the module is enabled, the value can be freely read. When the module is disabled, the register is clear-on-write and has to be read before the next attack.

18.2.6 WRITER

DMA DRAM writer.

Allows to fill DRAM with a predefined pattern using DMA.

Pattern

Provides access to RAM to store access pattern: *mem_addr* and *mem_data*. The pattern address space can be limited using the *data_mask*.

For example, having *mem_addr* filled with $[0x04, 0x02, 0x03, \dots]$ and *mem_data* filled with $[0xff, 0xaa, 0x55, \dots]$ and setting *data_mask* = $0b01$, the pattern [(address, data), ...] written will be: $[(0x04, 0xff), (0x02, 0xaa), (0x04, 0xff), \dots]$ (wraps due to masking).

DRAM memory range that is being accessed can be configured using *mem_mask*.

To use this module, make sure that *ready* is 1, then write the desired number of transfers to *count*. Writing to the *start* CSR will initialize the operation. When the operation is ongoing *ready* will be 0.

Register Listing for WRITER

Register	Address
<i>WRITER_START</i>	<i>0xf0002800</i>
<i>WRITER_READY</i>	<i>0xf0002804</i>
<i>WRITER_MODULO</i>	<i>0xf0002808</i>
<i>WRITER_COUNT</i>	<i>0xf000280c</i>
<i>WRITER_DONE</i>	<i>0xf0002810</i>
<i>WRITER_MEM_MASK</i>	<i>0xf0002814</i>
<i>WRITER_DATA_MASK</i>	<i>0xf0002818</i>
<i>WRITER_DATA_DIV</i>	<i>0xf000281c</i>
<i>WRITER_INVERTER_DIVISOR_MASK</i>	<i>0xf0002820</i>
<i>WRITER_INVERTER_SELECTION_MASK</i>	<i>0xf0002824</i>
<i>WRITER_LAST_ADDRESS</i>	<i>0xf0002828</i>

WRITER_START

Address: 0xf0002800 + 0x0 = 0xf0002800

Write to the register starts the transfer (if ready=1)

WRITER_READY

Address: 0xf0002800 + 0x4 = 0xf0002804

Indicates that the transfer is not ongoing

WRITER_MODULO

Address: 0xf0002800 + 0x8 = 0xf0002808

When set use modulo to calculate DMA transfers address rather than bit masking

WRITER_COUNT

Address: 0xf0002800 + 0xc = 0xf000280c

Desired number of DMA transfers

WRITER_DONE

Address: $0xf0002800 + 0x10 = 0xf0002810$

Number of completed DMA transfers

WRITER_MEM_MASK

Address: $0xf0002800 + 0x14 = 0xf0002814$

DRAM address mask for DMA transfers

WRITER_DATA_MASK

Address: $0xf0002800 + 0x18 = 0xf0002818$

Pattern memory address mask

WRITER_DATA_DIV

Address: $0xf0002800 + 0x1c = 0xf000281c$

Pattern memory address divisor-1

WRITER_INVERTER_DIVISOR_MASK

Address: $0xf0002800 + 0x20 = 0xf0002820$

Divisor mask for selecting rows for which pattern data gets inverted

WRITER_INVERTER_SELECTION_MASK

Address: $0xf0002800 + 0x24 = 0xf0002824$

Selection mask for selecting rows for which pattern data gets inverted

WRITER_LAST_ADDRESS

Address: $0xf0002800 + 0x28 = 0xf0002828$

Number of completed DMA transfers

18.2.7 READER

DMA DRAM reader.

Allows to check DRAM contents against a predefined pattern using DMA.

Pattern

Provides access to RAM to store access pattern: *mem_addr* and *mem_data*. The pattern address space can be limited using the *data_mask*.

For example, having *mem_addr* filled with [*0x04, 0x02, 0x03, ...*] and *mem_data* filled with [*0xff, 0xaa, 0x55, ...*] and setting *data_mask* = *0b01*, the pattern [(address, data), ...] written will be: [(*0x04, 0xff*), (*0x02, 0xaa*), (*0x04, 0xff*), ...] (wraps due to masking).

DRAM memory range that is being accessed can be configured using *mem_mask*.

To use this module, make sure that *ready* is 1, then write the desired number of transfers to *count*. Writing to the *start* CSR will initialize the operation. When the operation is ongoing *ready* will be 0.

Reading errors

This module allows to check the locations of errors in the memory. It scans the configured memory area and compares the values read to the predefined pattern. If *skip_fifo* is 0, this module will stop after each error encountered, so that it can be examined. Wait until the *error_ready* CSR is 1. Then use the CSRs *error_offset*, *error_data* and *error_expected* to examine the errors in the current transfer. To continue reading, write 1 to *error_continue* CSR. Setting *skip_fifo* to 1 will disable this behaviour entirely.

The final number of errors can be read from *error_count*. NOTE: This value represents the number of erroneous *DMA transfers*.

The current progress can be read from the *done* CSR.

READER_START

Address: $0xf0003000 + 0x0 = 0xf0003000$

Write to the register starts the transfer (if ready=1)

READER_READY

Address: $0xf0003000 + 0x4 = 0xf0003004$

Indicates that the transfer is not ongoing

READER_MODULO

Address: $0xf0003000 + 0x8 = 0xf0003008$

When set use modulo to calculate DMA transfers address rather than bit masking

READER_COUNT

Address: $0xf0003000 + 0xc = 0xf000300c$

Desired number of DMA transfers

READER_DONE

Address: $0xf0003000 + 0x10 = 0xf0003010$

Number of completed DMA transfers

READER_MEM_MASK

Address: $0xf0003000 + 0x14 = 0xf0003014$

DRAM address mask for DMA transfers

READER_DATA_MASK

Address: $0xf0003000 + 0x18 = 0xf0003018$

Pattern memory address mask

READER_DATA_DIV

Address: $0xf0003000 + 0x1c = 0xf000301c$

Pattern memory address divisor-1

READER_INVERTER_DIVISOR_MASK

Address: $0xf0003000 + 0x20 = 0xf0003020$

Divisor mask for selecting rows for which pattern data gets inverted

READER_INVERTER_SELECTION_MASK

Address: $0xf0003000 + 0x24 = 0xf0003024$

Selection mask for selecting rows for which pattern data gets inverted

READER_ERROR_COUNT

Address: $0xf0003000 + 0x28 = 0xf0003028$

Number of errors detected

READER_SKIP_FIFO

Address: $0xf0003000 + 0x2c = 0xf000302c$

Skip waiting for user to read the errors FIFO

READER_ERROR_OFFSET

Address: $0xf0003000 + 0x30 = 0xf0003030$

Current offset of the error

READER_ERROR_DATA7

Address: $0xf0003000 + 0x34 = 0xf0003034$

Bits 224-255 of *READER_ERROR_DATA*. Erroneous value read from DRAM memory

READER_ERROR_DATA6

Address: $0xf0003000 + 0x38 = 0xf0003038$

Bits 192-223 of *READER_ERROR_DATA*.

READER_ERROR_DATA5

Address: $0xf0003000 + 0x3c = 0xf000303c$

Bits 160-191 of *READER_ERROR_DATA*.

READER_ERROR_DATA4

Address: $0xf0003000 + 0x40 = 0xf0003040$

Bits 128-159 of *READER_ERROR_DATA*.

READER_ERROR_DATA3

Address: $0xf0003000 + 0x44 = 0xf0003044$

Bits 96-127 of *READER_ERROR_DATA*.

READER_ERROR_DATA2

Address: $0xf0003000 + 0x48 = 0xf0003048$

Bits 64-95 of *READER_ERROR_DATA*.

READER_ERROR_DATA1

Address: $0xf0003000 + 0x4c = 0xf000304c$

Bits 32-63 of *READER_ERROR_DATA*.

READER_ERROR_DATA0

Address: $0xf0003000 + 0x50 = 0xf0003050$

Bits 0-31 of *READER_ERROR_DATA*.

READER_ERROR_EXPECTED7

Address: $0xf0003000 + 0x54 = 0xf0003054$

Bits 224-255 of *READER_ERROR_EXPECTED*. Value expected to be read from DRAM memory

READER_ERROR_EXPECTED6

Address: $0xf0003000 + 0x58 = 0xf0003058$

Bits 192-223 of *READER_ERROR_EXPECTED*.

READER_ERROR_EXPECTED5

Address: $0xf0003000 + 0x5c = 0xf000305c$

Bits 160-191 of *READER_ERROR_EXPECTED*.

READER_ERROR_EXPECTED4

Address: $0xf0003000 + 0x60 = 0xf0003060$

Bits 128-159 of *READER_ERROR_EXPECTED*.

READER_ERROR_EXPECTED3

Address: $0xf0003000 + 0x64 = 0xf0003064$

Bits 96-127 of *READER_ERROR_EXPECTED*.

READER_ERROR_EXPECTED2

Address: $0xf0003000 + 0x68 = 0xf0003068$

Bits 64-95 of *READER_ERROR_EXPECTED*.

READER_ERROR_EXPECTED1

Address: $0xf0003000 + 0x6c = 0xf000306c$

Bits 32-63 of *READER_ERROR_EXPECTED*.

READER_ERROR_EXPECTED0

Address: $0xf0003000 + 0x70 = 0xf0003070$

Bits 0-31 of *READER_ERROR_EXPECTED*.

READER_ERROR_READY

Address: $0xf0003000 + 0x74 = 0xf0003074$

Error detected and ready to read

READER_ERROR_CONTINUE

Address: $0xf0003000 + 0x78 = 0xf0003078$

Continue reading until the next error

18.2.8 DFI_SWITCH

Register Listing for DFI_SWITCH

Register	Address
<i>DFI_SWITCH_REFRESH_COUNT</i>	<i>0xf0003800</i>
<i>DFI_SWITCH_AT_REFRESH</i>	<i>0xf0003804</i>
<i>DFI_SWITCH_REFRESH_UPDATE</i>	<i>0xf0003808</i>

DFI_SWITCH_REFRESH_COUNT

Address: $0xf0003800 + 0x0 = 0xf0003800$

Count of all refresh commands issued (both by Memory Controller and Payload Executor). Value is latched from internal counter on mode transition: MC -> PE or by writing to the *refresh_update* CSR.

DFI_SWITCH_AT_REFRESH

Address: $0xf0003800 + 0x4 = 0xf0003804$

If set to a value different than 0 the mode transition MC -> PE will be performed only when the value of this register matches the current refresh commands count.

DFI_SWITCH_REFRESH_UPDATE

Address: $0xf0003800 + 0x8 = 0xf0003808$

Force an update of the *refresh_count* CSR.

18.2.9 PAYLOAD_EXECUTOR

Executes the DRAM payload from memory

Instruction decoder

All instructions are 32-bit. The format of most instructions is the same, except for the LOOP instruction, which has a constant TIMESLICE of 1.

NOOP with a TIMESLICE of 0 is a special case which is interpreted as STOP instruction. When this instruction is encountered execution gets finished immediately.

NOTE: TIMESLICE is the number of cycles the instruction will take. This means that instructions other than NOOP that use TIMESLICE=0 are illegal (although will silently be executed as having TIMESLICE=1).

NOTE2: LOOP instruction will *jump* COUNT times, meaning that the “code” inside the loop will effectively be executed COUNT+1 times.

Op codes:

Op	Value
NOOP	0b000
LOOP	0b111
ACT	0b100
PRE	0b101
REF	0b110
ZQC	0b001
READ	0b010

Instruction format:

	LSB		MSB
dfi:	OP_CODE	TIMESLICE	ADDRESS
noop:	OP_CODE	TIMESLICE_NOOP	
loop:	OP_CODE	COUNT	JUMP
stop:	<NOOP>	0	

Where ADDRESS depends on the DFI command and is one of:

	LSB		MSB
	RANK	BANK	COLUMN
	RANK	BANK	ROW

Register Listing for PAYLOAD_EXECUTOR

Register	Address
<i>PAYLOAD_EXECUTOR_START</i>	<i>0xf0004000</i>
<i>PAYLOAD_EXECUTOR_STATUS</i>	<i>0xf0004004</i>
<i>PAYLOAD_EXECUTOR_READ_COUNT</i>	<i>0xf0004008</i>

PAYLOAD_EXECUTOR_START

Address: $0xf0004000 + 0x0 = 0xf0004000$

Writing to this register initializes payload execution

PAYLOAD_EXECUTOR_STATUS

Address: $0xf0004000 + 0x4 = 0xf0004004$

Payload executor status register

Field	Name	Description
[0]	READY	Indicates that the executor is not running
[1]	OVER-FLOW	Indicates the scratchpad memory address counter has overflowed due to the number of READ commands sent during execution

PAYLOAD_EXECUTOR_READ_COUNT

Address: $0xf0004000 + 0x8 = 0xf0004008$

Number of data from READ commands that is stored in the scratchpad memory

18.2.10 I2C

Register Listing for I2C

Register	Address
<i>I2C_W</i>	<i>0xf0004800</i>
<i>I2C_R</i>	<i>0xf0004804</i>

I2C_W

Address: $0xf0004800 + 0x0 = 0xf0004800$

Field	Name	Description

I2C_R

Address: $0xf0004800 + 0x4 = 0xf0004804$

Register Listing for CTRL

Register	Address
<i>CTRL_RESET</i>	<i>0xf0005000</i>
<i>CTRL_SCRATCH</i>	<i>0xf0005004</i>
<i>CTRL_BUS_ERRORS</i>	<i>0xf0005008</i>

CTRL_RESET

Address: $0xf0005000 + 0x0 = 0xf0005000$

Field	Name	Description
[0]	SOC_RST	Write 1 to this register to reset the full SoC (Pulse Reset)
[1]	CPU_RST	Write 1 to this register to reset the CPU(s) of the SoC (Hold Reset)

CTRL_SCRATCH

Address: $0xf0005000 + 0x4 = 0xf0005004$

Use this register as a scratch space to verify that software read/write accesses to the Wishbone/CSR bus are working correctly. The initial reset value of 0x1234578 can be used to verify endianness.

CTRL_BUS_ERRORS

Address: $0xf0005000 + 0x8 = 0xf0005008$

Total number of Wishbone bus errors (timeouts) since start.

SDRAM_CHECKER_RANDOM

Address: $0xf0007800 + 0x24 = 0xf0007824$

Field	Name	Description

SDRAM_CHECKER_TICKS

Address: $0xf0007800 + 0x28 = 0xf0007828$

SDRAM_CHECKER_ERRORS

Address: $0xf0007800 + 0x2c = 0xf000782c$

18.2.17 SDRAM_GENERATOR

Register Listing for SDRAM_GENERATOR

Register	Address
<i>SDRAM_GENERATOR_RESET</i>	<i>0xf0008000</i>
<i>SDRAM_GENERATOR_START</i>	<i>0xf0008004</i>
<i>SDRAM_GENERATOR_DONE</i>	<i>0xf0008008</i>
<i>SDRAM_GENERATOR_BASE1</i>	<i>0xf000800c</i>
<i>SDRAM_GENERATOR_BASE0</i>	<i>0xf0008010</i>
<i>SDRAM_GENERATOR_END1</i>	<i>0xf0008014</i>
<i>SDRAM_GENERATOR_END0</i>	<i>0xf0008018</i>
<i>SDRAM_GENERATOR_LENGTH1</i>	<i>0xf000801c</i>
<i>SDRAM_GENERATOR_LENGTH0</i>	<i>0xf0008020</i>
<i>SDRAM_GENERATOR_RANDOM</i>	<i>0xf0008024</i>
<i>SDRAM_GENERATOR_TICKS</i>	<i>0xf0008028</i>

SDRAM_GENERATOR_RESET

Address: $0xf0008000 + 0x0 = 0xf0008000$

SDRAM_GENERATOR_START

Address: $0xf0008000 + 0x4 = 0xf0008004$

SDRAM_GENERATOR_DONE

Address: $0xf0008000 + 0x8 = 0xf0008008$

SDRAM_GENERATOR_BASE1

Address: $0xf0008000 + 0xc = 0xf000800c$

Bits 32-35 of *SDRAM_GENERATOR_BASE*.

SDRAM_GENERATOR_BASE0

Address: $0xf0008000 + 0x10 = 0xf0008010$

Bits 0-31 of *SDRAM_GENERATOR_BASE*.

SDRAM_GENERATOR_END1

Address: $0xf0008000 + 0x14 = 0xf0008014$

Bits 32-35 of *SDRAM_GENERATOR_END*.

SDRAM_GENERATOR_END0

Address: $0xf0008000 + 0x18 = 0xf0008018$

Bits 0-31 of *SDRAM_GENERATOR_END*.

SDRAM_GENERATOR_LENGTH1

Address: $0xf0008000 + 0x1c = 0xf000801c$

Bits 32-35 of *SDRAM_GENERATOR_LENGTH*.

SDRAM_GENERATOR_LENGTH0

Address: $0xf0008000 + 0x20 = 0xf0008020$

Bits 0-31 of *SDRAM_GENERATOR_LENGTH*.

SDRAM_GENERATOR_RANDOM

Address: $0xf0008000 + 0x24 = 0xf0008024$

Field	Name	Description

SDRAM_GENERATOR_TICKS

Address: $0xf0008000 + 0x28 = 0xf0008028$

18.2.18 TIMERO

Timer

Provides a generic Timer core.

The Timer is implemented as a countdown timer that can be used in various modes:

- Polling : Returns current countdown value to software
- One-Shot: Loads itself and stops when value reaches 0
- Periodic: (Re-)Loads itself when value reaches 0

en register allows the user to enable/disable the Timer. When the Timer is enabled, it is automatically loaded with the value of *load* register.

When the Timer reaches 0, it is automatically reloaded with value of *reload* register.

The user can latch the current countdown value by writing to *update_value* register, it will update *value* register with current countdown value.

To use the Timer in One-Shot mode, the user needs to:

- Disable the timer
- Set the load register to the expected duration
- (Re-)Enable the Timer

To use the Timer in Periodic mode, the user needs to:

- Disable the Timer
- Set the load register to 0
- Set the reload register to the expected period
- Enable the Timer

For both modes, the CPU can be advertised by an IRQ that the duration/period has elapsed. (The CPU can also do software polling with *update_value* and *value* to know the elapsed duration)

Register Listing for TIMERO

Register	Address
<i>TIMERO_LOAD</i>	<i>0xf0008800</i>
<i>TIMERO_RELOAD</i>	<i>0xf0008804</i>
<i>TIMERO_EN</i>	<i>0xf0008808</i>
<i>TIMERO_UPDATE_VALUE</i>	<i>0xf000880c</i>
<i>TIMERO_VALUE</i>	<i>0xf0008810</i>
<i>TIMERO_EV_STATUS</i>	<i>0xf0008814</i>
<i>TIMERO_EV_PENDING</i>	<i>0xf0008818</i>
<i>TIMERO_EV_ENABLE</i>	<i>0xf000881c</i>

TIMERO_LOAD

Address: 0xf0008800 + 0x0 = 0xf0008800

Load value when Timer is (re-)enabled. In One-Shot mode, the value written to this register specifies the Timer's duration in clock cycles.

TIMERO_RELOAD

Address: 0xf0008800 + 0x4 = 0xf0008804

Reload value when Timer reaches 0. In Periodic mode, the value written to this register specify the Timer's period in clock cycles.

TIMERO_EN

Address: 0xf0008800 + 0x8 = 0xf0008808

Enable flag of the Timer. Set this flag to 1 to enable/start the Timer. Set to 0 to disable the Timer.

TIMERO_UPDATE_VALUE

Address: 0xf0008800 + 0xc = 0xf000880c

Update trigger for the current countdown value. A write to this register latches the current countdown value to value register.

TIMERO_VALUE

Address: $0xf0008800 + 0x10 = 0xf0008810$

Latched countdown value. This value is updated by writing to `update_value`.

TIMERO_EV_STATUS

Address: $0xf0008800 + 0x14 = 0xf0008814$

This register contains the current raw level of the zero event trigger. Writes to this register have no effect.

Field	Name	Description
[0]	ZERO	Level of the zero event

TIMERO_EV_PENDING

Address: $0xf0008800 + 0x18 = 0xf0008818$

When a zero event occurs, the corresponding bit will be set in this register. To clear the Event, set the corresponding bit in this register.

Field	Name	Description
[0]	ZERO	1 if a <i>zero</i> event occurred. This Event is triggered on a falling edge.

TIMERO_EV_ENABLE

Address: $0xf0008800 + 0x1c = 0xf000881c$

This register enables the corresponding zero events. Write a 0 to this register to disable individual events.

Field	Name	Description
[0]	ZERO	Write a 1 to enable the zero Event

18.2.19 UART

Register Listing for UART

Register	Address
<i>UART_RXTX</i>	<i>0xf0009000</i>
<i>UART_TXFULL</i>	<i>0xf0009004</i>
<i>UART_RXEMPTY</i>	<i>0xf0009008</i>
<i>UART_EV_STATUS</i>	<i>0xf000900c</i>
<i>UART_EV_PENDING</i>	<i>0xf0009010</i>
<i>UART_EV_ENABLE</i>	<i>0xf0009014</i>
<i>UART_TXEMPTY</i>	<i>0xf0009018</i>
<i>UART_RXFULL</i>	<i>0xf000901c</i>
<i>UART_XOVER_RXTX</i>	<i>0xf0009020</i>
<i>UART_XOVER_TXFULL</i>	<i>0xf0009024</i>
<i>UART_XOVER_RXEMPTY</i>	<i>0xf0009028</i>
<i>UART_XOVER_EV_STATUS</i>	<i>0xf000902c</i>
<i>UART_XOVER_EV_PENDING</i>	<i>0xf0009030</i>
<i>UART_XOVER_EV_ENABLE</i>	<i>0xf0009034</i>
<i>UART_XOVER_TXEMPTY</i>	<i>0xf0009038</i>
<i>UART_XOVER_RXFULL</i>	<i>0xf000903c</i>

UART_RXTX

Address: 0xf0009000 + 0x0 = 0xf0009000

UART_TXFULL

Address: 0xf0009000 + 0x4 = 0xf0009004

TX FIFO Full.

UART_RXEMPTY

Address: 0xf0009000 + 0x8 = 0xf0009008

RX FIFO Empty.

UART_EV_STATUS

Address: 0xf0009000 + 0xc = 0xf000900c

This register contains the current raw level of the rx event trigger. Writes to this register have no effect.

Field	Name	Description
[0]	TX	Level of the tx event
[1]	RX	Level of the rx event

UART_EV_PENDING

Address: $0xf0009000 + 0x10 = 0xf0009010$

When a rx event occurs, the corresponding bit will be set in this register. To clear the Event, set the corresponding bit in this register.

Field	Name	Description
[0]	TX	1 if a tx event occurred. This Event is triggered on a falling edge.
[1]	RX	1 if a rx event occurred. This Event is triggered on a falling edge.

UART_EV_ENABLE

Address: $0xf0009000 + 0x14 = 0xf0009014$

This register enables the corresponding rx events. Write a 0 to this register to disable individual events.

Field	Name	Description
[0]	TX	Write a 1 to enable the tx Event
[1]	RX	Write a 1 to enable the rx Event

UART_TXEMPTY

Address: $0xf0009000 + 0x18 = 0xf0009018$

TX FIFO Empty.

UART_RXFULL

Address: $0xf0009000 + 0x1c = 0xf000901c$

RX FIFO Full.

UART_XOVER_RXTX

Address: $0xf0009000 + 0x20 = 0xf0009020$

UART_XOVER_TXFULL

Address: $0xf0009000 + 0x24 = 0xf0009024$

TX FIFO Full.

UART_XOVER_RXEMPTY

Address: $0xf0009000 + 0x28 = 0xf0009028$

RX FIFO Empty.

UART_XOVER_EV_STATUS

Address: $0xf0009000 + 0x2c = 0xf000902c$

This register contains the current raw level of the rx event trigger. Writes to this register have no effect.

Field	Name	Description
[0]	TX	Level of the tx event
[1]	RX	Level of the rx event

UART_XOVER_EV_PENDING

Address: $0xf0009000 + 0x30 = 0xf0009030$

When a rx event occurs, the corresponding bit will be set in this register. To clear the Event, set the corresponding bit in this register.

Field	Name	Description
[0]	TX	1 if a tx event occurred. This Event is triggered on a falling edge.
[1]	RX	1 if a rx event occurred. This Event is triggered on a falling edge.

UART_XOVER_EV_ENABLE

Address: $0xf0009000 + 0x34 = 0xf0009034$

This register enables the corresponding rx events. Write a 0 to this register to disable individual events.

Field	Name	Description
[0]	TX	Write a 1 to enable the tx Event
[1]	RX	Write a 1 to enable the rx Event

UART_XOVER_TXEMPTY

Address: $0xf0009000 + 0x38 = 0xf0009038$

TX FIFO Empty.

UART_XOVER_RXFULL

Address: $0xf0009000 + 0x3c = 0xf000903c$

RX FIFO Full.
